Abstract. Digital pathology is the computer technology that allows the management of the information generated by the whole-slide scanners from a microscopic slide, encompassing the virtual microscopy. This paper proposes and describes the architecture of a secure collaborative platform that integrates a web pathology viewer with role-based access control. The proposed architecture is ensured by a shared medical repository that serves web pathology viewer with the medical images, using the DICOM standard. The system offers collaborative work session management tools as the managing of users, sessions, access control to sessions, and many others. Furthermore, the use cases related to telepathology and e-learning are presented.

Keywords. WSI, collaborative, digital pathology, PACS, DICOM, access control

1. Introduction

Digital pathology has gained popularity in the most recent years as a consequence of the proliferation of the Whole-slide Imaging (WSI) [1,2], replacing the traditional microscopes [3]. The digital era in the pathology field brought new features in the review process: the samples can be easily accessed from anywhere and anytime and at the same time as other users and then remotely reviewed and annotated. The improvements lie in the diagnostic accuracy and efficiency of the support systems. The handling of the samples becomes more secure as there is no deterioration in the image quality [4].

Digital pathology made available new methods to teach histology and pathology that was impossible until the digital revolution [5]. The digital replaces the old and expensive microscopes and simplifies the process in a way that all that is required is a device with internet access and a web browser for concurrent access to the same sample, either for teachers or students. Still, the regulation nowadays forces to protect the patient's data [6]. Therefore, the handling of these samples over the network requires strong access control and security protocols.

Digital pathology made available new methods to teach histology and pathology that was impossible until the digital revolution [5]. teachers or students. Still, the regulation nowadays forces to protect the patient's data [6]. Therefore, the handling of these samples over the network requires strong access control and security protocols.

Figure 1. Screenshot of the platform during a work session.

This paper proposes and implements a secure architecture for the management of digital pathology remote working sessions². The management platform provides means for a session creator to restrict and personalize permissions for the access and handling of medical images. The framework also integrates a pure web pathology viewer fully compliant with Digital Imaging and Communications and Medicine (DICOM) standard, the Dicoogle open-source project to support the WSI storage, and a web platform for the management of all the working sessions and their associated users. Furthermore, the introduction of a security layer [7] enables to control access policies in a non-secure environment, deploying an innovator multi-repository concept. The data management is assured by this accounting mechanism specially designed for medical imaging archives which creates the concept of virtual archives for each user.

2. Background

2.1. DICOM-PACS Universe

The evolution of the radiology regarding the digital paradigm let to the implementation of Picture Archiving and Communication Systems (PACS). PACS is an aggregation of hardware and software services that orchestrate acquisition, storage, and display of medical imaging data. All of the previous steps are integrated into digital networks supported by DICOM standard. PACS rely on DICOM, which is one of the most popular standards in the medical imaging field [8].

In 2010, microscopy was introduced in the DICOM, as a result of the rapid spread and adoption of the standard. The publication of the supplement 145 boosted the development of the automated whole-slide scanners [4]. However, the technology maturity level and initial vendor-lock positioning of scanners industry does not promote a fast adoption of DICOM-WSI in the first years.

Whole-Slide Images are specimen-centric, unlike the traditional DICOM information model, that are considered patient-centric where the specimen is not the

² Demo: <http://demo.dicoogle.com/pathobox>; Demo Video: <https://youtu.be/Mmsb25edcOo>

most relevant subject [9]. The most recent DICOM standard supplement dedicated to WSI specify the workflows regarding the preparation, acquisition, and storage of this kind of imaging objects [9].

2.2. Dicoogle

Dicoogle³ is an open-source PACS [10]. Its applicability encompasses different contexts as clinical, research and academic. Dicoogle's architecture follows a modular approach, allowing the development of new features over time.

The Dicoogle Software Development Kit (SDK) allows the addition of new features by third parties without the need to change the software core. The Dicoogle SDK provides interfaces that the developers need to implement to build a plugin⁴. Dicoogle, during the startup, automatically loads the modules contained in this directory and all the operations related to storage, querying and indexation become immediately available via its API.

3. Architecture Overview

Figure 2 shows the general architecture of the proposed system. Four main components can be identified: the PACS archive, the management platform (MP), the web viewer and the access control module.

Figure 2. Collaborative platform general architecture.

In this context, a working session is a live persistent document, that maintains synchronization between all users. The MP is where all the data, regarding sessions, users and their permissions, is stored. This component is independent of the viewer, so with little effort, other viewers can be attached to the management platform to support the working sessions.

The purpose of the MP is to give the user the necessary tools to manage his sessions, with the possibility to create user groups (that speed up the process of inviting users), define user permissions in the working sessions, define access control configurations to each session, insert new case studies and create new sessions. The MP handles the access to the working sessions at two different levels: controlling the access to the working sessions through user-defined parameters, such as access dates, invited users and their permissions; controlling the access to the case studies that the sessions are based on.

The users can be invited via two ways: email, where a personal invitation link to the session is delivered, with preemptively defined permissions; or through a public share-

³ Website: www.digoogle.com; GitHub: <https://github.com/bioinformatics-ua/dicoogle>

⁴ <https://bioinformatics-ua.github.io/dicoogle-learning-pack>

able link, up to a defined limit, which will be given no permissions to edit the session. These permissions can be changed live in the session.

The permissions on the session define which actions the user can perform concerning the image and the study, such as moving around the image or create annotations, and regarding the collaborative tools, such as inviting or kicking users from the session.

The MP controls the users in the session, registering who and how many users are connected, preventing the simultaneous usage of the same invitation link and limiting the number of users connected through a public link.

Given that the platform works over medical repositories, including personal archives that constitute sensitive information and therefore need to be compliant with the General Data Protection Regulation (GDPR), the access to the case studies needs to be controlled. In this case, access to the case studies is role-based and controlled by an existing accounting mechanism developed by Lebre et al. [7]. This mechanism is role-based, preventing users from accessing archives they should not have access to. The permissions can be extended to third-party entities allowing to create multiple virtual archives and share them amongst other users and institutions.

Upon logging in into the MP, a role is given to the user, defining which case studies he/she has access to. The user can upload to the platform his cases or the system administrator can grant this user access to existing archives.

Within a working session, the viewer, using the web link, determines the visualization mode to be used, retrieving the user's permissions and session's details from the MP and the specific medical case from the PACS archive. It has three visualization modes, all sharing the same basic visualization tools: live mode, the representation of the working session; replay mode, allowing to review all the actions on the working session; archive mode, the study case can be viewed without any of the collaborative features.

4. Use Cases

A collaborative paradigm in pathology enables the interaction and discussion by several users simultaneously, each in their own device. The collaborative system was designed to satisfy two usage scenarios, clinical and educational.

In the clinical field, the leader of the study can create a group of users from his peers to an easier attribution of permissions. Alternatively, the leader may specify or change the permissions of each member when establishing the working session. The replay mode will allow the peers to review actions performed and be able to keep up with the research. In the educational field, the groups could be formed with students or can be given the public link, allowing these users to follow along with the class. By changing the permissions of one of the attendees, the educator can, for instance, evaluate the ability of a specific student to detect critical regions in the study. Moreover, tasks for students can be defined. For instance, annotation of a working case that will be saved as a session than can be reviewed later by the evaluator.

On both cases, the framework virtualizes the concept of PACS archive. I.e., the management platform creates virtual sessions where the users only have access to the DI-COM objects that the creator of the session has previously defined. However, all of the DICOM objects are stored in the same archive. The framework provides then, the

capacity to share studies and instances among users belonging to distinct healthcare organizations or departments.

5. Conclusion

In the medical field, the imaging field represents a crucial tool in the quality of diagnosis. Sharing patient data between entities boosts the accuracy of decision making. In this line, collaborative work is a breaking-change in clinical decision-making. The collaborative paradigm addresses also educational purposes, allowing collaboration among professors and students.

This paper presents the architecture and use cases of a DICOM web digital pathology viewer with access control mechanisms integrated. The proposed framework creates the concept of collaborative sessions. However, the existence of such a framework requires a permission management system which led to the deployment of a management framework that promotes the resource sharing among users or institutions. The working sessions are virtual web viewers where an administrator can define which users can have access to which resources. These features turn the system institution-free and enhance telemedicine and remote diagnosis. Moreover, using pure web technologies, the system can be used anywhere, anytime, regardless of the operating system and without any prior installation.

Safer Surgery Checklist: Barriers in the Adoption of Tablets in Operating Room

Giuliana COLUSSI^{1a}, Gabriela GARCIA ^a, Maria GRANDE^a, Daniel LUNA^a

^a Health Informatics Department, Hospital Italiano de Buenos Aires, Argentina

Abstract. It is crucial that registering the checklist needs to be done synchronously and according to the care tasks within the operating room. Therefore, we aim to find out what are the difficulties that the surgical technicians have when checking the list and exploring potential barriers to implementing the use of tablets. Qualitative research was conducted based on focus groups, in-depth interviews and on-site observations until a full coverage of the topics was achieved. We detected that this problem includes technical aspects (connectivity, hardware and software issues), those related to workflow and logistics, those related with registration process, and those related to organization culture and power structure. Based on results, we developed a plan to solve problems detected.

Keywords. Checklist; Operative Surgical Procedure; Patient Safety; Qualitative Research

1. Introduction

In order to standardize care processes in the operating room, the World Health Organization designed a checklist with the advice of surgeons, anesthetists, nurses, and patient-safety experts from around the world [1]. It aims to reinforce established safety practices and promote communication and teamwork across multiple clinical disciplines.

Checklist's implementation during the surgical procedure is intended to work as a tool to improve patient safety, human factors, reduce the incidence of adverse events, morbidity and mortality [2] [3] [4].

However, evidence shows that there are some factors that prevent this procedure from being done on time and correctly [5], despite being a requirement of the Joint Commission International [6]. The barriers to the correct implementation of the surgical checklist are multifactorial and cover both cultural and structural aspects, including communication gaps, the benefit perceived by the user, lack of understanding of the procedures, the perceived ambiguity of the process and negative perceptions regarding operational efficiency, and others [7] [8].

In 2014 the Italian Hospital of Buenos Aires (HIBA), computerized the checklist to be used during the surgical process, and in 2015 the use of tablets was implemented so that the surgical technicians team can complete it from a mobile device, and thus be able to do it next to the patient. However, the use of the tablets was not maintained

¹ Corresponding author: Giuliana.colussi@hospitalitaliano.org.ar.

over time, and gradually ceased to be used for the checklist registration.

It is crucial that registering the checklist needs to be done synchronously and according to the care tasks within the operating room. Therefore, we aim to find out what are the difficulties that the surgical technicians have when checking the list and exploring potential barriers to implementing the use of tablets, in order to formulate solutions that guarantee the correct realization of it.

2. Methods

The HIBA is a center of high complexity located in the City of Buenos Aires. Every year performs 52,000 surgical procedures in its 41 operating rooms.

Qualitative research was conducted based on focus groups, in-depth interviews and on-site observations until a full coverage of the topics was achieved. Both the interviews and the focus groups were audio recorded for further analysis, protecting the identity of the participants who voluntarily participated through an informed oral consent. The research project was approved by the institutional ethics committee (CEPI # 5001). The study was performed in full agreement with current national and international ethical regulations.

Between November and December of 2018, 2 focus groups were held, one with the morning shift group and the other one with the afternoon shift group. A total of 41 surgical technicians participated. A tool from the Lean Change Management was used as a triggering material for the investigation. This tool consists in expressing which is the summoning problematic [9]. Then each member, individually, writes in a piece of paper the reasons why they think this is happening. Next step, the reasons are collected, grouped by categories and the different issues that arise begin to be discussed among all the participants. This way, participant's feedback is shared, eliminating biases and generating perceptions of greater value, where possible solutions arise from the group itself.

A group interview was carried out with 2 key participants: the surgical technicians coordinator and the management and update coordinator of the surgery department. Three surgical processes were observed on different days, schedules and operating rooms. Also electronic devices, access to networks and the software involved during the surgical processes were reviewed. The observations were carried out in the central operating room, covering all the tasks performed by surgical technicians, especially focusing on the checklist registration process. The information was systematized in field newspapers, elaborating a dense description [10] through interviews and focus groups.

The analysis process was carried out simultaneously with the information collection process, through the coding and categorization of information, based on a constant comparison process. The categories were built taking into account the central research questions such as the findings that emerged from the same focus groups, interviews and observations, building a descriptive framework that helps contextualize the collected data [11].

3. Results

Emerging categories according to the checklist completion arise from the combination of three employed techniques, that allowed greater wealth in the understanding of the phenomenon. We found three main dimensions. These dimensions account for technical aspects expressed in problems ranging from device's hardware, software, and problems with Wifi signal. We also found workflow related problems, manifested as logistic and organization issues, as well as problems related to the process at registering the checklist, to the organizational culture and about power structure.

3.1 Technical aspects

We evidenced difficulties or barriers in the inquiry that were related to technical aspects associated with checklist registration, which includes connectivity, software and hardware problems.

Connectivity: We detected connectivity problems as unstable range of Wifi inside each operating room, that causes logged out, browsing slow, or lose information loaded. This could make the registration process problematic and longer times.

"often the wifi is wrong and that's it, if you don't have Wi-Fi ... it doesn't work"

Software problems: In order to access checklist interface, surgical technicians must enter to the Electronic Health Record (EHR) from the tablet. In this sense the screen does not adapt to the resolution of used device, making zooming and scrolling necessary. This creates which creates possibilities of error when accidentally touching buttons and when they need to click many times to enter the surgical episode of each patient.

"It is cumbersome to have to enlarge and shrink the image to check option"

"I had to be enlarging the screen, you went to the next step and you had to enlarge it...if there was an application in a standard size, that's it, the size would not be a problem"

Hardware problems: Tablets were slow and usually freeze, and users have difficulty writing on them:

"The tablet's size creates difficulties for writing" "The icons looked very small"

3.2 Workflow

Within this dimension we find three barriers, one is related to dynamics inside the operating room, another refers to operational logistics of tablets and the last one refers to registration itself. Dynamics inside the operating room: in the record of the observations, we noted that operating rooms have 2 desktop computers, one is exclusively used by anesthesia team, expressed explicitly, and the other one, although it was not expressly announced, was constantly used by surgeons. This makes difficult to synchronize the checklist because surgical technicians must wait until computer was available.

*"getting to the computer is very difficult and the computer is far from patient",
"in order be able to register something that is done at a certain moment you need to get away
from the patient, turn their backs at them. It is
very careless and when they register the data, the computer is busy"*

Tablets operational logistics: responsibility generated by using a device that is not their

own but belongs to the institution is explained. In order to use them, a process to ensure safety and cleanliness of tablets had to be respected. Circuit becomes disruptive in routine surgical technicians tasks, since they have to go to storage and complete a form when borrowing the devices, taking responsibility for them, which consumed too much time and made them uncomfortable to continue with another tasks. In addition, tablets were not always available because they were stored without enough battery, and chargers were missing.

“you were going to ask for tablet, you opened it, it had no battery, you had to go back to ask for a charger, and there were no chargers”, “They (surgeons) asked for charger to another use (phone charge), I don’t know if they would take it home, or leave it there. Doctors have their radio, they never have battery and they have the same charger plug as tablets”, “A lot of liability for possible losses between surgeries while we have to prepare material”

Check List Registration: problematic of synchronous register of checklist is given by a set of topics related to assistencialist aspect of surgical technicians work. On one hand, presence of a mobile device such as tablets could hinder dynamics their work, since they need to have both hands free to specify their care tasks with patient, since interrogation until ensuring availability of necessary supplies on operating table.

“At patient’s admission we have many things to do, we cannot have it (tablets) in our hands”, “One difficulty is having to have it during surgeries”

On the other hand, check list is generic and unique for different services and types of surgeries, which implies that all fields present in it do not always apply, or some are missing, or order items may not correspond to a specific workflow.

3.3 Organizational culture and power structures in operating room

Transversally to addressed problems, an underlying category refers to organization culture and power structures in operating room. We observed that power structures within operating room set out priorities on devices use of such as computers and tablet chargers. Sometimes surgical technicians relegate tasks to comply with requests from surgeons in the ward, for example bringing their cell phone, taking a picture of surgical marking on patient. Likewise, although correct application of check list is a responsibility of the entire operating room team, surgical technicians adopt this task as their own.

4. Discussion and Conclusion

We explored difficulties of surgical technicians that arise checklist procedure. We detected that this problem includes technical aspects (connectivity, hardware and software issues), those related to workflow and logistics, those related with registration process, and those related to organization culture and power structure.

Based on preliminary results, we solved connectivity issues, we installed more Wi-Fi access points in operating rooms, and we developed a plan to replace obsolete devices. Regarding the software, we plan to develop a new mobile application that responds to specific registration needs of surgical technicians team. However, solving technical aspects would not solve all difficulties detected. Despite our plan with informatics issues, additionally, it will be convenient to attend organizational and

cultural factors, concordant with literature [8].

Workflow problems could be solved by installing a bedside post next to patient to hold tablets and allowed hands free. This would ensure that surgical technicians have a device exclusively for them, and able to prevent wasting time in withdrawal and return.

Finally, we consider that could be convenient to redesign checklist according to specific context in which it will be used, as Raman recommends [12]. According to organization culture and power structure, it would be desirable to work with the entire Department of Surgery to raise awareness among all members of operating room about the importance of correct completion of checklist on patient safety, following the importance of the team's commitment is highlighted [13], as a collective responsibility.

Sensor-Based Decision Support for the Allocation of Patient Attendants in Hospitals

Sascha GFELLER^a, Philip KYBURZ^a, Kai-Uwe SCHMITT^{b,c}, Thomas BÜRKLE^a,
Jürgen HOLM^a and Murat SARIYAR^{a,1}

^a*Bern University of Appl. Sciences, Dept. Medical Informatics, Switzerland*

^b*Bern University of Appl. Sciences, Dept. Health, Academic-Practice-Partnership, Switzerland*

^c*Insel Gruppe, University Hospital Bern, Switzerland*

Abstract. In hospitals, patient attendants are often necessary in order to closely monitor patients with high risk of self-endangering actions and reactions. However, such additional monitoring of patients is associated with high costs. In this paper, we describe a technical infrastructure for monitoring the patient's activities, which helps to assess whether an attendant should be requested. It was central to for us to use non-invasive sensors and to exploit a variety of patient data such as heart rate, micro-activity and oxygen saturation.

Keywords. clinical decision support; sensors; micro-activity; patient sitters

1. Introduction

Monitoring inpatients in hospitals is an ever-increasing challenge, as the amount of multimorbidity rises with aging population. Especially in acute care settings, many adverse events, such as delirium or a psychotic episode, are not related to the actual reason for being hospitalized. Patients who develop a delirium are disoriented, confused and/or unable to understand their current situation. In the elderly patients, a delirium can be superimposed on dementia. As a result, such patients might suddenly remove medical devices (such as venous access devices, tubes, catheters, electrodes, cables, etc.), they show stress reactions and/or attempt to stand up. Currently, in nursing practice, it is often difficult to predict whether and when a patient will develop such states that require close monitoring [1, 2]. There are certain known risk factors (such as age, drugs used, etc.), but often health professionals can only rely on their experience for taking any precautions or initiating any measures [3].

Attendants can be nursing trainees, medical students and non-health care professionals [4, 5]. Hospitals usually have a pool of such staff. Their job is to permanently watch the patient at risk and to intervene if required. On a normal ward, the options for interventions are limited to, e.g., calming down the patient by talking or calling additional nursing staff for help. Such additional monitoring of patients is

¹ Corresponding Author, Murat Sariyar, Bern University of Applied Sciences, Quellgasse 21, CH2502 Biel/Bienne, Switzerland; E-mail: murat.sariyar@bfh.ch.

associated with high costs. According to internal information from a Swiss university hospital (approximate bed size 900) yearly costs for patient attendants can sum up to 60 full-time nurse equivalents.

As the request for an attendant must be made several hours in advance, a positive decision can result in attendants sitting beside a sleeping patient, thus wasting resources. A case study at a hospital in Ohio reported that using a risk-based digital assessment tool for regularly allocating attendants can reduce the working hours without increasing the adverse events, indicating that there is potential in reducing costs [6].

Our goal was to provide and examine a sensor-based technical infrastructure monitoring the patient's activities, which might be helpful to assess whether an attendant should be requested. It was central for us to use non-invasive sensors and to exploit a variety of patient data such as heart rate, micro-activity and oxygen saturation.

2. Methods

2.1 Review of the literature

We conducted a literature research in Cinahl, PubMed, Web of Science and Google Scholar with a focus on the work of patient attendants, the decision process of employing them, sensors for detecting and preventing adverse events, and clinical decision support systems for allocating patient attendants. Keywords were identified in particular through preliminary discussions with stakeholders. These were then entered in various combinations:

- "sitter" or "attendants"
- ("sitters" OR "attendants") AND "risks"
- "constant observers"
- "constant observers" AND "risks"
- "inpatient" AND "fall detection"
- "patient monitoring" AND "fall detection"
- "mattress sensor care"
- "health data sensor"
- "patient monitoring sensor"
- "vital data sensor"

2.2 Approaches considered

In order to get insights into the actual work of patient attendants, a semi-structured questionnaire for interviews with attendants was prepared and eight interviews were conducted. The questions were related to the preparation and training for the job, contents of the tasks tackled, subjective assessments of the job, and opinions to the use of sensors in the context of the job. Inclusion criteria for the interview were: working at least half a year as patient attendant within the last two years, speaking German or English, working in a Swiss hospital, being of age.

To derive the requirements of a sensor-based monitoring system we developed several use-cases. In addition, we composed scribbles inspired from the Design-Thinking approach to visualize the processes itself and potential problems from the perspective of a patient attendant [7]. Based on that input, we implemented a web

application to integrate the sensor data using the agile Scrum approach [8] in ten one-week sprints. We applied the JavaScript framework vue.js and loopback for the frontend and the backend, respectively.

3. Results

The results of our literature research showed a variety of definitions of the concept “patient attendant” [9,10]. Many different settings have been reported that require different forms of monitoring and interventions. This was corroborated by the eight interviews we have conducted. Some attendants just observed, others had to intervene, others used a lot of communication with the patient. In most cases, there were no trainings beforehand. Attendants had to deal with different medical conditions such as delirium, dementia, schizophrenia, suicidality, alcohol problems, etc. Interventions comprised calming down the patient, preventing the patient from standing up or make sure that a member of clinical staff is available swiftly. Approximately half of the deployments were futile because no interventions were required. The study participants indicated that sensors monitoring patient mobility and/or attempts to leave the bed might be beneficial.

We developed an evaluation matrix for sensors currently available on the market. Main criteria were measured parameters, running time, interfaces, how data is gathered (extend of invasiveness), costs, and certification as a medical device. Based on these attributes, we decided to use two complementary and nearly non-invasive sensors. One sensor is the *Mobility Monitor*™ (momo) of Compliant Concept, which monitors micro-movements of the patients in their bed by placing a sensor under the mattress. The system can detect accurately agitation and bed-leaving events. The other sensor (*Everion*™) from Biovotion is placed on the patients arm and measures pulse, skin temperature, oxygen saturation, respiratory rate, and some more parameters. For the momo sensor a REST API is available, for Everion a JAVA SDK has to be used in order to read the data.

The overall architecture of our prototype, called *SensorLink*, is given in Figure 1. Both sensors are queried every 10 seconds using the corresponding API. We combined the data of both sensors with clinical parameters into one single backend and provide interactive graphical outputs in order to assess whether a patient needs more monitoring. An example output of the front end is given in Figure 2. Interactivity in the graphical outputs is achieved by using the ApexCharts.js library for visualiations.

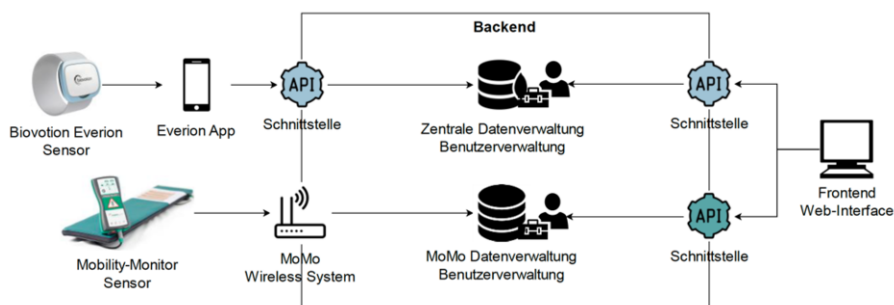

Figure 1. Overview on the prototypical sensor network system with two sensors (Everion and the Momo sensor) that provide data via different interfaces to the backend for display on a web interface.

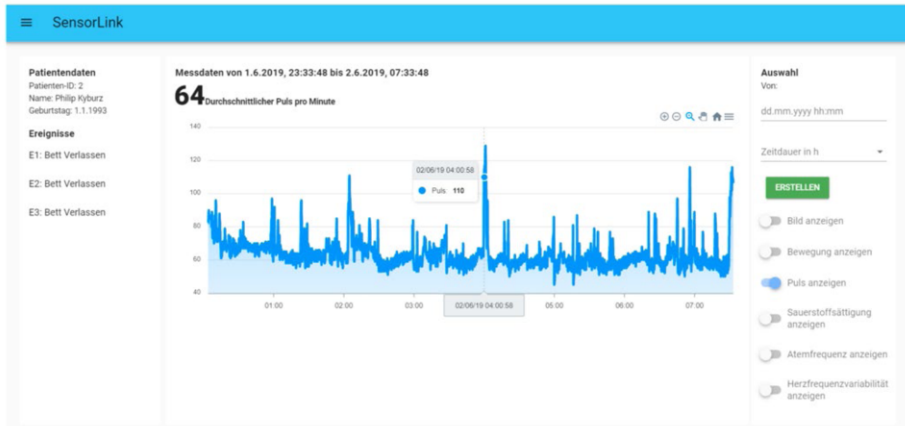

Figure 2. The graphical user interface of the SensorLink system. Here, the pulse trajectory of one night is shown in the main panel. The peak pulse value is at 110 and the average value throughout the night was 64.

The data in Figure 2 was collected by installing the sensors and the system at the medical informatics laboratory in Bienne/Switzerland with the aim to validate our solution. The co-authors SG and PK slept two days each in the laboratory. Central events, such as leaving the bed, are given at the left panel of the graphical interface. In the right panel, different criteria can be selected, e.g., measurement period, micro-activity, pulse, heart frequency variability, etc. The results for this selection are provided in the main panel. The graphics are interactive and aligned with each other based on the time stamps, which allows to monitor several parameters at desired time points.

4. Discussion

Currently, various sensor-based wearables, external sensors and even mobile video monitoring are available [11,12]. However, such solutions are frequently not apt for either reducing the amount of complications or for improving the decision efficiency regarding patient attendants' placements [13]. Especially, inappropriate decision and bad user experience associated with such additional systems pose serious problems [14]. To tackle these problems, non-invasive sensors data should be used together with rule-based reasoning and machine learning [15]. We have provided a first step in that direction.

The experiences in our project showed that it is rather cumbersome to individually integrate the diverse sensors. A decision-making system that uses many different sensors should use a comprehensive gateway solution that enables plug and play of those sensors. One commercial solution (<https://www.leitwert.ch>) provides an IoT middleware for managing and configuring such a gateway. It allows to collect data on a local server, which paves the way to use wearable medical devices in health care settings. Clocking of the different sensors is also a relevant issue, as the clock pulse can

vary between sensors. Further, it should be taken account that the amount of data generated by many sensors in short time intervals indicate that cloud-based solutions should be taken into consideration for scalability reasons.

We have gained first insights into the possible advantages of increased information on patients and suitable graphical summaries for the decision concerning placement of patient attendants. It is crucial, however, to prove the benefits of such a decision support tool for those who decide in practice. This requires a proper implementation study to evaluate the impact in a real-world setting. Central outcomes are acceptability, adoption, appropriateness, costs, feasibility, and sustainability [16]. Our goal is to conduct an implementation study with an extended version of our prototype, using a sensor gateway and machine learning components that do not just condense information but deliver advice whether a request of a patient attend is adequate or not.

Smart Ageing: Digital Solutions for Future Care

Anthony MAEDER^{a,1} and Gary MORGAN^a

^a*College of Nursing & Health Sciences, Flinders University, Adelaide, Australia*

Abstract. We propose a framework for discourse on digital solutions to support consumers and carers in delivery of health care and services for aged persons, based on a major needs analysis conducted across 56 diverse business entities in Australia. The resulting framework was based on two major identified domains: "Ageing in Place" for independent living situations, and "Ageing with Care" for managed aged care facilities. The paper describes the process used and the intermediate outcomes which enabled the framework to be synthesized. It is anticipated that the framework could be used to inform future scoping studies and to enable collaborative design, implementation and delivery of appropriate smart ageing digital solutions.

Keywords. Ageing, health services delivery, models of care

1. Introduction

It is well established that the age profile of world population is shifting rapidly towards a significantly higher proportion of aged persons than previously. The World Economic Forum has estimated that by 2050 more than 20% of world population will be aged 60 years and older [1]. In Australia (typical of developed countries) the proportion is even higher: it has been estimated that by 2046, 22% of the population will be aged 65 years and older, and that average life expectancy will be 85 years with 19% of older people (i.e. over 4% of population) being aged 85 years or older [2].

This change in the essential nature of our population will have profound impact, stimulating transformational changes underlying health care mechanisms. Today's older citizens wish to remain living in their own homes and to pursue an active lifestyle as long as possible, with appropriate support where necessary [3]. Those who require assisted living and clinical management through the health care system, expect that services reforms which will ensure optimal quality of life can be enjoyed in those circumstances [4]. We need to develop a variety of approaches to deal with this transformation, some of which will undoubtedly incorporate digital technologies.

Prior work has provided landscape commentary on opportunities for technology-delivered health care support for ageing citizens by appropriate technologies [5] and from clinical perspectives [6]. A common emphasis in these domains is the maintenance of independence and quality of life for subjects of care [7]. The consequential impact of these trends on health technology markets has also been characterized [8].

The research study summarised here was intended to provide a qualitatively validated clarification of major health services delivery needs for individuals of a future

¹ Corresponding author: A. Maeder, Email: anthony.maeder@flinders.edu.au

ageing society which can be potentially addressed by digital solutions. These major needs may be identified by the subjects-of-care themselves, or may be known to the providers of care services who deal directly with individuals: both groups constitute a body of end-users for the needs-derived solutions.

Before developing such solutions as these, it is important to understand their scope and to leverage common elements of them to derive the best outcomes. This could be expediently achieved by using a high level framework for considering approaches to developing digital solutions such as these: the major end-user needs identified here provide a basis for describing such a framework. We do not claim uniqueness for the framework but we believe that if similar exercises were undertaken, there would likely be a degree of commonality due to the diversity of the stakeholder sectors represented.

2. Methods

During February to October 2017 structured interviews were conducted with 56 Australian business entities representing a wide cross section of organisations involved with services for ageing. These included companies and not-for-profits engaged in community and aged care, hospital and acute care, primary care, nursing and allied health, finance, insurance, technology, software, built environment and urban design. Further consultations involved local and state government departments and peak professional bodies operating in the ageing sector, as well as ageing consumers directly.

Interviews were commenced with a short description of the context and purpose of the study. Interactive interviews followed, with a conversational approach adopted to enable free ranging inputs to be collected. Interview durations ranged from 30 mins to 2 hrs, and in most cases were conducted 1-to-1 between one of the authors and an informed senior executive representing the participating organisation. In some cases a second interviewee was present but in all cases the vast majority of responses were obtained from the primary participant.

A pro forma interviewing instrument based on prior work was developed to elicit problem statements and responses. The instrument contained the following discussion prompts:

- alignment of organisation with Ageing population sectors and situations;
- perceived major business problem statement and significance to organisation;
- actions currently being considered or already taken to address the problem;
- success criteria and need for collaboration and resources to progress solution;
- potential adoption and deployment settings within the organisation portfolio;
- strategic perspective on business impact of solving problem (2-5-10 years).

Conversational responses were captured verbatim from participants in written format. These were subsequently independently summarised using a simplifying terminology derived by a commonly used wordcloud formulation method, which extracted essential and repeated content from the conversational records. These condensed responses were subjected to topic clustering using concept-distance measures associated with the terminology, to extract common themes.

3. Results

From the topic clustering process, three distinctive end-user sectors were identified, which constitute domains of mutual interests spanning the overall ecosystem for a future ageing society:

Individual consumers and their personal circle of other persons, who are self-managing their ageing with support from both informal (e.g. family or friends) and professional (e.g. allied health workers) carers and the wider community within which they are situated (e.g. religious or social groups).

Community and aged care provider organisations and numerous associated service delivery agencies who are addressing and managing the needs of ageing clients, through services delivered in the home (e.g. cleaning, excercise), or through services delivered in residential managed care settings for those clients unable to care for themselves (e.g. feeding, medication).

Corporate or Government organisations, including clinical professionals, suppliers of health systems and technology solutions, developers and funders/payers responsible for business and infrastructure design and planning, and policy makers/influencers (e.g. bureaucracies, consultancies).

Two major thematic areas cutting across all three domains were discerned for development of digital technology solutions, from categorisation of the problem statements and significant recurring content descriptions from the interviews:

Ageing in Place, where consumers wish to continue living independently, in their own accommodation setting and maintaining responsibility for their own health status by accessing external sources of support. This will contribute to extending the years of healthy ageing and quality of life, as well as retaining longer engagement of ageing persons generally in economic and societal activities.

Ageing with Care, where it is necessary for consumers to live in conditions of clinical management, within specialised ageing facilities having associated inhouse health care professional support. This will provide platform systems for enhancement of key business processes and capabilities, improving consumer orientation of the current community and aged care business landscape, and aligning with needs to operate in a digitally informed knowledge environment.

For Ageing in Place, the dominant needs for solutions were identified as follows:

- Personal Wellness, with information gathered from about daily health related lifestyle habits of an individual, as well as summary data from digital monitoring sources and records of health check events.
- Community Connections, with a social networking online environment to enable individuals to establish and maintain a personalised set of community based group interactions and event participations.
- Adverse Event Reduction, using a “Health Smart Home” platform system for continuous surveillance of occupants, with multimodal sensing and pattern analysis to prompt alerts if anomalous situations are detected.

For Ageing with Care, the dominant needs for solutions were identified as follows:

- Personal Health Trajectories, representing and modelling of an individual’s ‘health trajectory’ based on health records and contributed data, mapping their advance through the ageing life course.

- Consumer Care Portal, a software system integrating information across service providers aligned with health data derived client profiles, and sharing health history and choices with clients/carers. Chronic Disease Management, via a generic software system including data collection and management, analysis of trends and recommendations on actions related to health condition self-care.

These findings are summarised in Table 1 below. While there could have been further less prominent topic areas extracted, to perhaps constitute a secondary layer of minor elements in the framework, the strength of consensus achieved by those identified here was sufficient to confirm them as dominant.

Table 1. Ageing digital technology solutions framework

Domain	Ageing in Place	Ageing with Care
Individual / Patient	Personal Wellness	Personal Health Trajectory
Community / Carers	Community Connections	Consumer Care Portal
Corporate / Clinicians	Adverse Event Reduction	Chronic Disease Management

4. Discussion

The focus of this work was an approach to enable us to identify and describe the needs and issues of older people and care providers, and which allows us to work collaboratively to design, implement and deliver solutions to those who need to apply them or use them. Through the coordination of research and development activities addressing these needs across diverse disciplines, organisations and sectors, innovative solutions can be developed which will create impact at scale.

This framework approach provides a set of channeled elements through which can be addressed the challenge of selecting and developing appropriate digital technology solutions to achieve the following high value benefits which participants indicated:

- Optimise the health and support the independence of older people, and thereby reduce the cost burden of care, by designing integrated solutions that focus on the person and their individual health circumstances.
- Empower older citizens to self-manage their health while ageing, to the greatest extent possible, with improved wellness and enablement while living independently and in communities, and provide for their eventual care in health facilities by equipping the clinical sector with integrated and comprehensive toolsets for appropriate and timely care.
- Address the business transformation needs of aged care and services providers, using living laboratory co-design models, to ensure solutions are appropriate, usable by customers and the workforce, and able to be integrated into wider systems, and validate their effectiveness at population scale such that they can be deployed widely.
- Develop transformational ‘ageing well’ approaches across the continuum of wellbeing, health and care services, which will improve the quality of life for ageing individuals and more generally enrich communities through the increased engagement of a previously excluded sector in the ageing population.

Feedback from interviewees included some broader aspirational elements as well as the specific needs analysis, which could not be categorized as precisely. These included adopting holistic viewpoints on health, living meaningful and purposeful lives, balancing increasing consumer expectations against diminishing services and choice, difficult to navigate the health system, complexity of integrating technologies.

5. Conclusions

The abovementioned benefits are consequential on the provision of appropriate technology solutions in the particular care setting. In the case of Ageing in Place, the wide range of potential technologies [9] must be tempered by their careful selection and application, to ensure success in their adoption and achievement of utility for purpose [10]. Further consideration will be necessary to address the challenges of data management and systems architecture [11] in this type of setting, as these are still far from being standardised. In the case of Ageing with Care, the overarching issue of integration and interoperability of component sub-systems and data flows [12] must be solved, harmonizing new solutions and current systems to enable care collaboration [13]. The Australian focus of this research may be seen as a limitation, but should nevertheless be comparable with the situations of many other high-income countries. Constructing a framework distilled from many lengthy and detailed interviews was seen as a beneficial way to provide scaffolding to support repetition of the process elsewhere. This approach should be of strong interest to the community and aged care sector to enable high level strategic planning and prompt social and economic flow-on impacts to its supporting sectors, to the health care system broadly, and finally to society at large.

^d Univ. Lille, CHU Lille, EA7365 GRITA, F-59000 Lille, France

Abstract. Clinical decision support systems (CDSS) fail to prevent adverse drug events (ADE), notably due to over-alerting and alert-fatigue. Many methods have been proposed in the literature to reduce over-alerting of CDSS: enhancing post-alert medical management, taking into account user-related context, patient-related context and temporal aspects, improving medical relevance of alerts, filtering or tiering alerts on the basis of their strength of evidence, their severity, their override rate, or the probability of outcome. This paper analyzes the different options, and proposes the setup of SPC-CDSS (statistically prioritized and contextualized CDSS). The principle is that, when a SPC-CDSS is implemented in a medical unit, it first reuses actual clinical data, and searches for traceable outcomes. Then, for each rule trying to prevent this outcome, the SPC-CDSS automatically estimates the conditional probability of outcome knowing that the conditions of the rule are met, by retrospective secondary use of data. The alert can be turned off below a chosen probability threshold. This probability computation can be performed in each medical unit, in order to take into account its sensitivity to context.

Keywords. Adverse drug events, Clinical decision support systems, data reuse.

1. Introduction

Adverse drug events (ADEs) are the most common type of iatrogenic injury. It is commonly admitted that coupling a clinical decision support system (CDSS) with a computerized order entry system (CPOE) may prevent ADEs [1]. But for current CDSS, over-alerting is an important issue: too numerous and inappropriate alerts may interrupt the clinicians' workflow and induce alert-fatigue [2,3], anger or annoyance [4]. This may prevent CDSS from improving patient safety [3,5]. As a consequence, up to 96% of alerts are overridden by prescribers [2,6–10], mainly because of poor appropriateness [11,12]. Unfortunately, appropriate alerts may be perceived as useless [2] and then overridden, but followed by actual ADEs [13–16]. The objective of this work is to propose a new approach to improve the ability of CDSS to prevent ADEs.

¹ Corresponding Author: emmanuel.chazard@univ-lille.fr

2. Material and methods

We first performed a narrative review of the tracks that have been proposed in the scientific literature, to reduce the over-alerting and alert-fatigue of CDSS, by searching for scientific papers in the Medline database, without time limit (keywords: CDSS, alert-fatigue, over-alerting). We also performed a recursive search including papers cited by those papers, and additional keywords. We then classified and discussed the tracks exposed in those papers. We finally proposed a new approach named SPC-CDSS (see below), in accordance with the results.

3. Results

3.1. Narrative review

In order to decrease over-alerting and alert-fatigue, it has been proposed to improve the way the CDSS interacts with the prescriber, and notably to improve the way the alerts are displayed [4], to provide the users with relevant instructions for post-alert medical management [3,17–19], and to involve non-medical healthcare professionals [6]. Some works also proposed to take into account the context of the drug prescription: user-related context (task, workflow, knowledge, preferences, medical unit) [2,20–22] and patient-related context (demographic data, risk factors) [3,17,20,21]. The temporal aspects have been identified as an important aspect: half of the prescribing errors occur on the first day of stay [14], the repetition of alerts has to be handled [9,20,21,23], as well as the kinetic of laboratory parameters [24].

It has also been proposed to improve the medical relevance of rules. One important track is to filter or tier the alerts by taking into account the strength of evidence [3,20,21]. It has been also proposed to ask medical experts to tier the alerts function of the severity of the potential outcome [3,5,6,20,21,25–27]: this approach seems to bring good results [5,25,27], but the experts hardly agree on the way to classify the rules [5,28]. Another option is to turn off rules that have the highest override rates [5,20,21,29]: this is efficient and mechanically decreases the override rate [29], but other studies demonstrated that most alert overrides were inappropriate [13–16].

Finally, given an ADE prevention rule, the conditional probability of ADE knowing that the conditions of the rule are met could be used to turn a rule on or off. This feature is largely asked by the physicians [3,20,21]. However, those approaches are still not implemented, although the reuse of electronic health records could enable to automatically estimate the conditional empirical probabilities of ADEs [30–33].

3.2. Proposal of SPC-CDSS

We propose to implement SPC-CDSS, which stands for “Statistically prioritized and contextualized clinical decision support systems”. The main idea is that, when a SPC-CDSS is implemented in a medical unit, it first reuses actual clinical data, and automatically searches for traceable outcomes (e.g. “INR>5”). Then, for each rule trying to prevent this outcome (e.g. “vitamin K antagonist & quinolone → risk of increased INR”), the SPC-CDSS automatically estimates the conditional probability of outcome, knowing that the conditions of the rule are met. In case of low probability

(the threshold can be customized), the corresponding alerts are automatically turned off (“statistically prioritized”). Moreover, this computation is performed in each medical unit, in order to take into account its sensitivity to context (“statistically contextualized”). This notion of context is a statistical proxy for latent undocumented variables, such as patients’ characteristics (e.g. some conditions, admission ground), organizational characteristics (e.g. monitoring policies), and physicians’ characteristics (e.g. knowledge about drugs, specialty, risk aversion) [30].

4. Discussion

Being able to compute the empirical probability of outcome for each ADE prevention rule may allow for two main benefits, that have been tested [30,33,34]. The first benefit could be to turn off some rules which empirical probability is below a chosen threshold (“A” arrow on Figure 1). Many CDSS rules are inappropriate [11,12], but experts hardly agree on which rule should be turned off [5,28]. The second benefit could be to show empirical evidence to the physicians to improve their adherence to the remaining alerts (“B” arrow on Figure 1). Indeed, too many appropriate rules are overridden by users [13–16]. Moreover, such information is requested by many physicians [3,20,21].

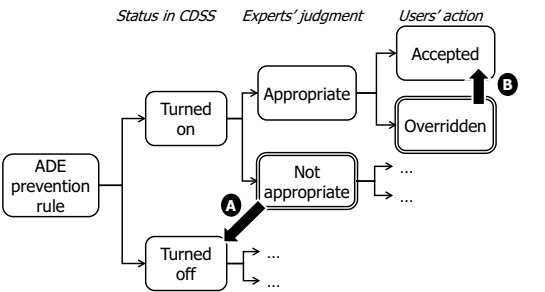

Figure 1. Expected benefits of SPC-CDSS: (A) turning some rules off, and (B) making rules more acceptable

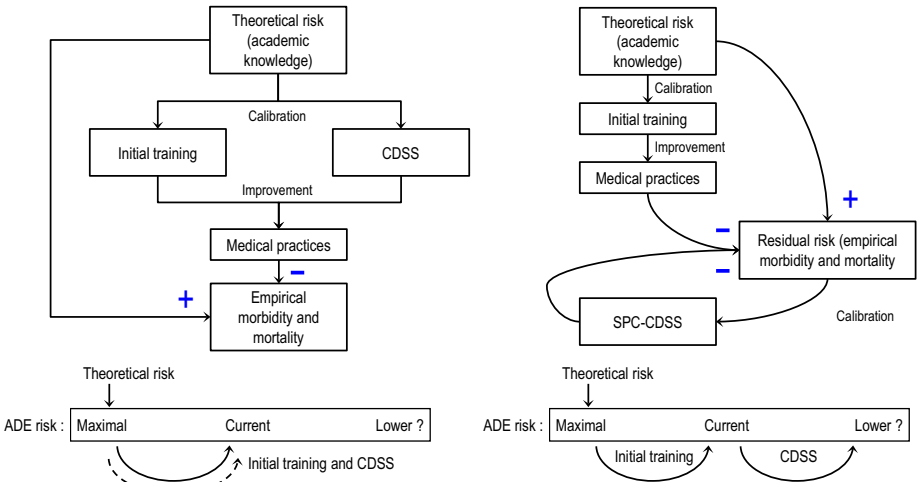

Figure 2. Left: current paradigm for ADE prevention. Right: proposed paradigm for ADE prevention.

The current paradigm for ADE prevention relies on the idea that CDSS should be calibrated based on the current academic knowledge (left part of [Figure 2](#)). But the physicians have also been initially trained on the basis of this knowledge. Consequently, the CDSS alerts are redundant with their own knowledge, and are useless. We propose to consider that the empirical morbidity and mortality are a residual risk, i.e. the maximal theoretical risk minus the benefits of the physicians' training. We then propose (right part of [Figure 2](#)) to use those empirical probabilities to calibrate the SPC-CDSS. Then, the SPC-CDSS alerts would be able to handle situations that have not been properly prevented by the initial training of the physicians. In terms of ADE risk, these considerations are summarized at the bottom of [Figure 2](#).

The present proposal should be tested and evaluated using actual clinical data. It also rises new issues, such as the threshold to choose, the variability between physicians, and the medical staff turnover. Finally, other solutions may be proposed to consider the final user's point of view.

Tackling Polypharmacy: A Multi-Source Decision Support System

Guilherme REDEKER^{a1} and Juliana BOWLES^a

^a*School of Computer Science, University of St Andrews, St Andrews KY16 9SX, UK*

Abstract. Managing the use of multiple medicines, also known as polypharmacy, is a challenge for physicians, pharmacists and patients alike, and is a particular concern for patients with multiple chronic conditions (aka multimorbidity). Patients with multimorbidity are often required to take a considerable number of medications for their different ongoing conditions, and managing/revising these medications effectively is a challenge. There is a need to periodically rearrange drugs taking into account patient's preferences and avoiding adverse drug reactions. We present an incremental, constraint solver based framework for a clinical decision support system that makes it possible to check drug prescriptions using information from multiple sources, including a constraint database and patient records. We illustrate how it can be used to manage clinical conditions while reducing polypharmacy problems and undesired side effects in a patient-centric approach.

Keywords. Polypharmacy, multimorbidity, constraint solvers, clinical decision support systems

1. Introduction

Polypharmacy can be defined as the concomitant use of multiple medications by a patient [1] [2], and is commonly linked to the treatment of multiple chronic diseases, also known as *multimorbidity*, which occurs with the highest prevalence in the elderly [3]. In addition, the use of many drugs simultaneously to treat different diseases is not always clear and may not match patient expectations and preferences [3] [4]. It is important that the use of various medications is safe and effective [5], and this may become questionable when the risks of medication combinations outweigh the benefits.

Studies have indicated that there are risks associated with the use of multiple medications, which include drug interactions and adverse drug reactions [6] [7]. Drug interactions have a negative outcome when the reaction between drugs has, for instance, a toxic effect or decreases the effect of one drug [6]. An adverse drug reaction is defined as any undesirable medical occurrence caused by a pharmaceutical product but not necessarily related to treatment [8] and may occur for different reasons, such as the wrong dose, drug or route [9]. Studies have shown that over half of the hospital admissions and between 25% to 50% of outpatient care arise from adverse drug reactions which could have been mitigated [10].

The complexity of taking decisions when treating patients can be a significant challenge, especially in the presence of polypharmacy which invariably combine many

¹ Guilherme Redeker, E-mail: gr60@st-andrews.ac.uk.

factors/variables. Additionally, treatments should be personalised and the patient's individual preferences included in the decision process. The position we take is that, specially in the case of complex decision making, automated tool support is essential. Our approach combines medical knowledge with formal methods techniques to search for and compute optimal solutions for managing the treatment of patients with complex needs. This paper is structured as follows: we describe the proposed framework in Section 2 and illustrate how our approach works in Section 3. We conclude the paper with some overall comments and future work in Section 4.

2. Proposed Framework

To support physicians in making appropriate decisions, we propose a clinical decision system framework to check and manage constraints between drugs, exams, and diseases and take into account patient preferences. The solution consists of five parts: the Electronic Medical Record (EMR) interface, the Knowledge interface, the Knowledge database, the Inference engine and the Decision maker

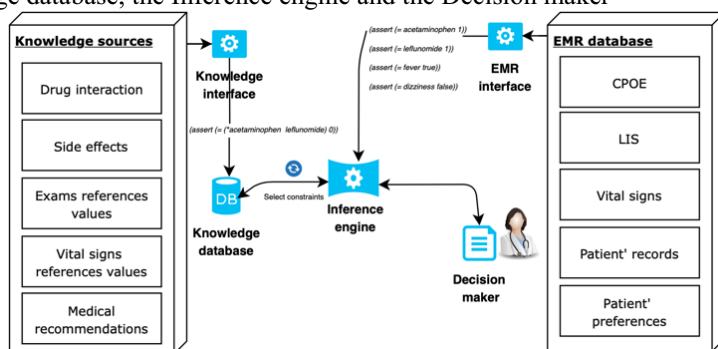

Figure 1. Multi-Source Decision Support System Framework.

The framework shown in Figure 1 takes constraint data from the knowledge sources and patient data from the EMR which are processed independently. The information from both sources is used in the Inference engine, which is responsible for merging both patient and constraint data. The Inference engine checks in the knowledge database if there are constraints that need to be solved according to the patient information then automatically searches for alternative solutions without constraints and displays them for the doctor to decide the appropriate prescription.

2.1. Knowledge interface and database

There are different sources of constraints in knowledge sources which can be used in the Inference engine. To standardize the link between the Inference engine and its sources, we propose a generic knowledge interface. This interface enables the retrieval of data about different constraint types such as drug interactions, side effects, alternative drugs, exam and vital sign reference values. Developing a generic interface will allow users to connect new and different types of constraint sources.

The knowledge interface operates in three steps: receive, process/convert and deliver. The data can be *received* from different channels. Each channel is for a specific type of constraint (e.g., for drug interaction data) and has a custom layout. The data

received by the hub is *converted* into a formal model illustrated in Figure 1 on the *assert* text between the knowledge interface and database, which is compatible with the Z3 [11] solver. *Delivery* is divided into *checking* (searching the knowledge database to see if a specific constraint is already recorded) and *inserting*. If a constraint is already recorded it is discarded, otherwise the system inserts it in the knowledge database to be used by the Inference engine.

2.2. EMR interface

The EMR interface deals with different types of patient data to link the information between the EMR database and Inference engine. Initially, the EMR interface was developed to receive all available information from the patient such as Computerized Physician Order Entry (CPOE) which includes drug prescriptions, laboratory results from the Laboratory Information System (LIS), Vital Signs and Patient Records. The EMR interface also has a channel to receive information on patient preferences. For example, there are medications with side effects such as headache, dizziness or drowsiness, that patients may want to avoid. In these situations, physicians should select drugs which avoid particular side effects.

Similar to the knowledge interface, after receiving information from the EMR, the EMR interface processes the data in three steps: identify, process/convert and deliver. In the first step, the hub *identifies* the type of data (e.g., exam results, drug prescriptions, vital signs or patient records). In the next step, the hub *converts* the data into a formal showed in Figure model to be compatible with the Z3 [11] solver, showed in Figure 1 between the EMR database and interface. Finally, the information is *delivered* to the Inference engine.

2.3. Inference engine and decision maker

The Inference engine was proposed to create links between the knowledge database and patient data, so that it is possible for example to search for drugs that do not have undesired side effects. The compiler receives patients' clinical information and selects the related constraints on the knowledge database to define solutions using the constraint solver Z3 [11].

Firstly, the compiler receives the data from the EMR interface and checks if there are constraints that need to be solved. Secondly, after receiving patient data, a query is executed in the knowledge database based on the received data (e.g., Acetaminophen and Leflunomide drug prescription), to find the linked constraint (in this example, the drug-drug interaction, drug-adverse reaction, drug-disease interaction and drug-food interaction). Finally, if constraints are found for the patient data, the compiler is executed to solve or manage them. As a result, the compiler returns advice to physicians, the decision maker, which takes into account a number of important variables and allows the physician to choose the most appropriate treatment plan to be adopted for a given patient.

3. Practical example

To illustrate how our approach works, we present an extended hypothetical example taken from [5] about a 69 years old man. The patient arrives in hospital after a fainting

and seizures episode and complaining about arm pain and dizziness. The physician checks the patient's previous data on the EMR as shown on the first row of Table 1. Thereafter the physician requests a blood glucose test, verifies the blood pressure and prescribes Dextrose 10% and Electrolyte 500 ml and Codeine phosphate (7,5 mg) + Acetaminophen (300 mg) as shown in the second row of Table 1.

During the consultation, the patient data (previous and new records) is sent from the EMR to the EMR interface and sent to the Inference engine.

Table 1. Patient data

Current medical history	Result exams	Drugs	Patient' preferences
(Previous) Frequent falls Dementia – mixed Alzheimer's disease /alcohol abuse	(Previous) BP 120/74 mmHg Blood glucose test 90 mg/dL	(Continuous use) Trazodone 150 mg Thiamine 50 mg Bendroflumethiazide 2.5 mg	(Previous) Patient reports: feeling tired and short of breath
(New records) Fainting episode, seizures	(New records) BP 132/74 mmHg Blood glucose test 125 mg/dL	(New records) Codeine phosphate (7,5 mg) + Acetaminophen (300 mg) Dextrose 10% and Electrolyte 500 ml	(New records) Patient reports: Feeling arm pain and dizziness

Given the drug interactions and medical recommendations from the knowledge source, the Inference engine checks the constraints from the knowledge database against the patient data and highlights the relevant constraints as in the three tables below.

Table 2. Constraint drug interaction data

Drug	Drug	Interaction	Severity
Trazodone	Codeine phosphate	risk of a rare but serious condition called the serotonin syndrome, which may include symptoms such as confusion, hallucinations, seizures, blurred vision	Moderate
Trazodone	Bendroflumethiazide	lowering blood pressure	Moderate

Table 3. Medical recommendations

Drug	Condition	Recommendation
Dextrose 10%	blood glucose test 125 mg/dL	May cause hyperglycemia

Table 4. Side effects

Drug	Side effects	Used for the following conditions (associated conditions)
Trazodone 10%	dizziness	Alcohol Dependence, Alzheimer's Disease (AD), Dementias
Bendroflumethiazide	dizziness	High Blood Pressure
Codeine	dizziness	Pain, Acute, Severe Pain, Moderate Pain

Thereafter, the physician interactively manages these constraints with the Inference engine. To solve the first interaction in Table 2 between Trazodone and Codeine phosphate, the system shows to the physician the drug interaction and lists alternative drugs to manage the problem. The alternative drugs are selected from the knowledge database according to the associated conditions shown in Table 4. For all listed drugs, the system shows all the possible constraints, for example, interactions with other drugs or side effects that should be avoided according to patient preferences. The alternative drugs are sorted from the best to the more intricate options, that is, from the smallest to the biggest number of related constraints. The physician can also decide

to exclude a drug from the prescription or prescribe a drug that is not listed, for example, to minimise a side effect.

Moreover, if the physician decides to change/include/exclude a drug, the system reloads in real-time the constraints based on this decision. Otherwise, the system keeps the existing constraints and flags the chosen drugs in order to avoid repeated alerts in case of reloading. The same process is repeated to solve the medical recommendations in Table 3 and the side effects in Table 4. The process ends when there are no constraints to be solved, which does not mean that all restrictions have been solved, but that all decisions regarding the constraints have been made.

4. Conclusion

In this paper, we presented the vision of a framework to support physicians to make the appropriate decisions considering different types of drug constraints and interactions, and respecting patient preferences. The framework is enabled to receive multiple data sources combining patient and constraint records. As a clinical decision support system, our proposed automated solution only offers advice and the final decision remains with the physician. We demonstrated how the system can give advice to manage drug conflicts for a realistic but hypothetical example, highlighting the importance of gathering medical evidence and knowledge in decision making. In future work, we intend to fully develop, implement and evaluate the proposed solution.

Abstract. Patients with diabetes are often worried about having low blood glucose because of the unpleasant feeling and possible dangerous situations this can lead to. This can make patients consume more carbohydrates than necessary. Ad-hoc carbohydrate estimation and dosing by the patients can be unreliable and may produce unwanted periods of high blood glucose. In this paper we present a system that automatically estimates and dispenses the amount of juice (or similar) according to the current patients' blood glucose values. The system is remotely accessible and customizable from a chatbot, exploits sensors and actuators to dispense the necessary amount of liquid carbohydrates. It relies on a cloud solution (Nightscout) to acquire the patient's blood glucose values, which are constantly updated thanks to a commercial wearable continuous glucose monitor (CGM).

Keywords. Diabetes, Hypoglycemia, Carbohydrates, Cyber-Physical Systems, Internet of Things

1. Introduction

Measuring and managing blood glucose concentration is a key element in diabetes care, especially in type 1 diabetes. Since the first real time continuous glucose monitor (CGM) was provided for patients in 2001 [1], its relevance in both ambulatory diabetes care and clinical research has increased over the years [2]. Decreasing size, weight, complexity and cost of CGM sensors/devices have increased usage and dissemination [3]. CGMs have helped patients to improve their quality of life, by increasing their confidence in self-management of their disease.

In diseases such as diabetes, due to the availability of low cost technologies, well-educated patients, or engaged relatives, it has become possible to formulate, develop and distribute solutions that aim to answer specific needs in managing the disease, based on the patients individual situation [4].

¹ Corresponding author: email: pietro.randine@uit.no

In this study we show how it is possible to integrate patient-initiated solutions such as Nightscout [5], different sensors, mobile technologies and actuators, as concrete tools in patients’ daily life. The system referred to as “The House of Carbs”, was developed in collaboration with patients, to help them in one of the daily challenges in insulin-treated diabetes, namely low blood glucose episodes (hypoglycemia). The goal was to design a solution that can automatically dose an estimated amount of juice (or similar) from a reservoir to a glass, when required. The motivation is to avoid serious hypoglycemia situations and in preventing subsequent high levels of blood glucose (hyperglycemia) due to intake of more carbohydrates than necessary. We aim in stabilizing the blood glucose and avoid the “Roller coaster effect”, when the blood glucose is fluctuating between levels outside the normal range.

This paper is organized as follows: first we describe the methods used, and then we present the designed prototype and data from 2 months of use by two patients. The paper concludes with limitations and challenges for integrating sensors and actuators in a cyber-physical system for people with type 1 diabetes.

2. Methods

A literature review was conducted for mapping the available systems for managing hypoglycemia. The outcomes of this review and a patient-involvement approach were then used to define the system functionalities and requirements. Patients’ needs and expectations were also used to improve the software during the prototype testing phase.

Figure 1 shows the conceptual overview of the system, and how it interacts with external hardware and software components.

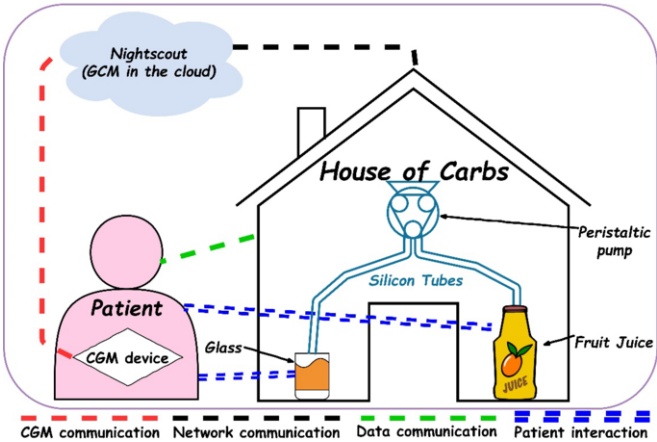

Figure 1: House of Carbs – a conceptual overview

Nightscout provides the real time data necessary to detect the hypoglycemic episodes and to evaluate the result achieved by the liquid carbohydrates delivery.

The patient must be an active part of the system, (s)he will have to insert the silicon tube inside the juice container and glass. Furthermore, the patient needs to provide the information about the juice’s content of carbohydrates and the web address of the Nightscout platform. In addition, (s)he is responsible for proper maintenance and use of the system, e.g. if the glass is removed from the system, the consequent assumption is

that the patient has drunk its content, and it needs to be replaced with a new glass before the next delivery.

3. Results

3.1. The prototype “House of carbs”

We built a fully functioning prototype using a Raspberry Pi 3 and an add-on board to control two high-power DC motors. The “House of carbs” includes an additional chatbot application to remotely control the hardware (e.g., clear the pump, remotely turn off the machine), define system parameters (e.g., carbohydrate content and amount of juice present, Nightscout address, units), and send notifications (e.g., “dose ready to be picked up”, “glass removed”), see Figure 2.

Figure 2: The prototype “House of Carbs”, based on communication with Dexcom G4 CGM and the Nightscout platform.

The system reports its status and the blood glucose values through a LCD display. The detection of the glass represents a critical issue in this system, and this is done by IR sensor. In case the glass is not detected, the system will block any juice distribution and users will receive a notification about the missing glass via the chatbot.

3.2. Treatment of hypoglycemia and prevention

A common approach to treat hypoglycemia is the 15/15 rule [6] (eat 15 grams of carbohydrate and wait 15 minutes), especially effective when using liquid carbohydrate sources [7]. This rule suggests checking the blood glucose value after 15 minutes and repeating the procedure if the glucose value is still under 3.9 mmol/L (70 mg/dL). The proposed system was designed together with real users, revealing the importance of automatically detect hypoglycemic episodes and deliver carbohydrates. The amount of carbohydrates was made personalizable, and the users can choose the amount of delivered carbohydrates (e.g. 20g instead of 15g). According to their suggestion, the system allows patient to request carbohydrates when expecting hypoglycemia, especially

relevant before an intense activity (e.g., physical activity) [8] or for safety reason before activities that may be risky (e.g. driving a car) [1].

3.3. Testing

The trial ran for two months involving two persons with type 1 diabetes. During this period the system logged 3116 different CGM readings and distributed 52 doses of carbohydrates. The system delivered either 15 or 20 grams of carbohydrates each time, based on the patient’s preferences. Table 1 presents the summary of these distributions.

Table 1: Successful juice distribution divided by patient and dose type (hypoglycemic or request)

Patient no	Carbs (g)	Total doses	Description	Value
1	15	9	Average hypoglycemic glucose value detected before the dose (mean ± SD)	3.48 ± 0.51 mmol/L
			Average glucose value after approx. 15 minutes (mean ± SD)	4.17 ± 0.79 mmol/L
	20	20	Average hypoglycemic glucose value detected before the dose (mean ± SD)	3.56 ± 0.43 mmol/L
			Average glucose value after approx. 15 minutes (mean ± SD)	4.13 ± 1.08 mmol/L
2	20	2	Average hypoglycemic glucose value detected before the dose (mean ± SD)	3.9 ± 0 mmol/L
			Average glucose value detected after the dose (mean ± SD)	4.7 ± 0 mmol/L
1	15	6	Average glucose value detected before dose request (mean ± SD)	4.75± 0.59 mmol/L
			Average glucose value after approx. 20 minutes (mean ± SD)	4.17 ± 1.38 mmol/L
	20	15	Average glucose value detected before dose request (mean ± SD)	4.85 ± 0.62 mmol/L
			Average glucose value after approx. 19 minutes (mean ± SD)	4.77 ± 0.83 mmol/L

4. Discussion

Health systems involving sensors and actuators need to be robust and adaptable to unexpected conditions and subsystem failures [9]. However, no component is perfectly reliable, and the physical environment will produce unexpected conditions.

The presented system integrates the open source diabetes-monitoring tool Nightscout, that has an informational and educational purposes only. Thus, the CGM data from Nightscout were the unique source of information in this system – which only was made to present future possibilities. All the designed functionalities are dependent

of this data, and when no data are received from Nightscout, the system is not able to provide these functionalities. Additionally, to maximize the accuracy of the system, the sensors connected to Nightscout must be calibrated according to the device producer's instructions. It is important to make it clear that the test period was short, the number of subjects were limited, and the patient participants have more than 20 years of diabetes experience and involved in different diabetes research projects.

4.1. Practical limitations

Designing such a system requires several assumptions. For example, that the source of carbohydrates is a safe and efficient liquid, the target glass has a capacity that can hold the maximum delivered dose, and both the source and target containers need to be clean due to hygienic reasons. Also, the entered settings need to be accurate for the system to deliver the right doses. If the user enters incorrect information (e.g., the carbohydrates content of the juice), the system may not help the user to achieve a healthy blood glucose level. Furthermore, the chatbot component of the system can potentially be accessed by anyone and therefore additional security solutions is needed to avoid abuse or misuse.

5. Conclusion

The main contribution of this research is demonstrating the design of a practical system able to monitor and prevent hypo- and hyperglycemia. The system has been designed using a patient driven approach, and integrates some already existing components.

The absorption of glucose into the bloodstream was shown to be effective for the two test-persons, after one or more delivered doses, in average after 15-20 minutes. They were satisfied with the use of the system and even surprised how it was able to stabilize the blood glucose. No hyperglycemia episodes or "Roller coaster effect" were caused by the system.

Update on the DMP, the French Nationally Shared Medical Record: Did We Make It?

Abstract. Different countries have solved the problem of care coordination by implementing a nationwide centralized framework of clinical information sharing with “new” secure online care records stored in specifically created platforms. The French DMP initially launched in 2006, relaunched in 2010, and re-relaunched in 2016 follows this model. After a difficult start and some governmental actions to promote its adoption, the DMP has been nationally deployed in November 2018. New features have been developed (creation of DMPs for children, management of minors’ rights, addition of living wills, notification of the first access of any healthcare professional), and financial incentive measures have been implemented. In September 2019, over seven million people had a DMP in France. In 18 months, we observed a significant increase of GPs feeding (from 0.7% to 20.9%) and consulting (from 1.6% to 44.8%) DMPs.

Keywords. Personal Health Records, Electronic Health Records/utilization, Patient Access to Records, Patient Participation, Mobile application

1. Introduction

Patients suffering of chronic diseases and related morbidities are currently managed in multiple settings by numerous healthcare professionals. Care is thus currently strongly fragmented and care coordination among the different healthcare professionals is complex. As a result, care management may be not effective and sometimes harmful to the patient [1]. The potential of electronic health records (EHRs) and other health information technology (HIT) tools to facilitate information flow at care transitions has been described [2]. In particular, these tools allow the different care providers to share the same information about a patient’s condition which allows to access crucial information in emergency room and optimizes the quality of care, reduce adverse drug reactions considered as the leading causes of morbidity and mortality in health care, and decreases health care costs by improving care relevance and not duplicating diagnostic tests. However, while EHRs are necessary, they are not sufficient to guarantee care coordination because non-interoperable EHRs and vendors’ expensive custom interfaces are hindering health information exchanges [3].

¹ Corresponding Author, brigitte.seroussi@aphp.fr.

Different countries have implemented a nationwide centralized framework of clinical information sharing to solve the problem of care coordination relying on the development of “new” secure online care records stored in specifically created platforms [4]. Adoption of these medical records has historically been poor and governmental actions were taken to promote their uptake. For instance, the DMP or “Dossier Médical Personnel”, currently “Dossier Médical Partagé”, has been relaunched in France in 2010 after a first start in 2006 and a first stop six months later due to security concerns [5]. It has also been re-launched in 2016 because of the poor uptake after the first relaunching (only 520,000 DMPs and about a coverage of 1.5% of the target population). At this time, the DMP program governance was transferred to the French national health insurance or CNAM (instead of the national technical agency in charge of HIT systems interoperability or ASIP Santé) and acted by the 2016 French Health Act.

Since 2016, new functionalities have been developed to improve the uptake of the “new” DMP, including the creation of DMPs by patients themselves, the automatic post of health data derived from insurance claims at the creation of DMPs (giving some medical contents to DMPs), the publication of a mobile app, and the organization of large public communication campaigns to inform patients and more widely involve citizens. These new features have been tested between December 2016 and August 2018 in nine pilot French departments with a good success [6]. This paper describes the evolution of the DMP program since August 2018, and specifically after the DMP official national deployment in November 2018 by both the French Ministry of Health and the French national health insurance’s director.

2. Methods

Originally, the DMP project was designed to support care coordination. All care providers may populate their patients’ DMP (discharge summaries, lab results, radiology reports, etc.). However, only care providers authorized by a DMP’ owner may access and read his/her DMP contents. To promote the national deployment of the DMP program, new functionalities have been developed to improve the quality of services provided by DMPs, along with the implementation of financial incentive measures varying with the different types of healthcare providers.

First, a huge work has been done by the French national health insurance with EHR vendors and care professionals to resolve remaining technical issues and promote the smooth interoperability of the DMP and EHR systems (almost all private physicians and hospitals have been accompanied by French national health insurance technical agents to help them upgrading their EHR systems). In addition, new features have been implemented such as the creation of DMPs for children, the management of minors’ rights (although under the responsibility of their legal representatives who are in charge of managing their DMP, minors may hide information to their parents with the support of an adult and in relationship with their general practitioner, GP), and the creation of a DMP chapter to collect advance directives (living wills). Besides, since DMPs are technically open to all healthcare professionals (except to those that have been explicitly excluded by the patient) to allow emergency accesses by any healthcare professional if necessary, the patient owner of a DMP is now notified of the first access of any healthcare professional to his/her DMP, in addition of this access being tracked in the DMP journal of accesses (only accessible to the patient and his/her GP). Finally,

a second version of the DMP app has been developed to improve interface ergonomics and usability.

Financial incentives have been implemented to accompany the deployment of the DMP program. Because pharmacists were very good to create the patient pharmacological record (DP), the French national health insurance offered them one euro per DMP created (nurses are the next on the list to get this incentive). DMP compatibility with EHRs used by private practitioners is now a prerequisite to get the ROSP (“Rémunération sur Objectifs de Santé Publique) that accounts to a maximum of 3500 euros per year. Biologists are also encouraged to use DMP-compatible HIT tools and they may receive from 5,500 to 10,000 euros per year (according to their levels of activity) when pushing biological reports / lab results in DMPs. Hospitals and private clinics may consider entering the nationwide HOP’EN program (HOP’EN builds on healthcare institutions digital transformation and modernization, the aim being that by 2022, whatever their status, size, and activity, they could bring their HIS to the maturity level necessary to address the new challenges of the health system defragmentation) and get revenues when they post discharge summaries in their patients’ DMP. Finally, nursing homes are also supported to use a DMP-compatible information system and to push post emergency liaison records in DMPs (they can receive up to 2,500 euros).

3. Results

Whereas there were 580,000 DMPs in June 2016, and 930,000 DMPs by the end of October 2017, there were seven million DMPs on September 15th, 2019. Currently, 10,000 DMPs are created every week. Figure 1 displays the evolution of DMP creation over the time. The acceleration of DMP creation after the national deployment of the program is visible. DMPs are mostly created in French national health insurance offices (45%), pharmacies (35%), and by patients using the DMP website on Internet.

Figure 1. Evolution of DMP creation visualizing the acceleration of the process after the national deployment of the DMP program.

DMP contents essentially come from private clinics and hospitals inputs. Currently, 400 out of the 3000 French care structures are pushing discharge summaries in DMPs (24 university hospitals out of a total of 32 nationwide). Besides, there is a significant increase of DMP feeding by GPs (from 0.7% to 20.9% in 18 months), and a significant increase of DMP consultation by doctors (from 1.6% to 44.8% for GPs, and from 0.1% to 7.3% for other medical specialists). The case of pharmacists is also noticeable with an increase of DMP consultation from 0.0% to 11.3%. Currently, and for political reasons (there is still no consensus between the French national health insurance and biologist unions on how, when, and which levels of incentives should be provided), biologists remain less involved in DMP creation, population, and consultation. Table 1 displays the evolution of DMP population and consultation according to the type of care practitioners.

Table 1. Evolution of DMP population and consultation according to practitioners types in 18 months.

Type of care practitioners	Number of care practitioners nationwide	January 2016 - December 2016				September 2018 - August 2019			
		Populating DMPs	%	Consulting DMPs	%	Populating DMPs	%	Consulting DMPs	%
General Practitioner	52 641	383	0,7%	840	1,6%	10 996	20,9%	23 567	44,8%
Medical Specialist	54 555	35	0,1%	56	0,1%	1 629	3,0%	3 993	7,3%
Masseur-Physiotherapist	67 860	19	0,0%	39	0,1%	98	0,1%	1 126	1,7%
Nurses	93 206	33	0,0%	126	0,1%	132	0,1%	815	0,9%
Other professions	77 562	3	0,0%	11	0,0%	144	0,2%	1 130	1,5%
Medical Biology Laboratories	3 864	6	0,2%	5	0,1%	12	0,3%	10	0,3%
Pharmacies	21 510	1	0,0%	3	0,0%	542	2,5%	2 437	11,3%

A new DMP mobile app has been developed to improve the display of all the documents contained in the DMP. A totally updated interface has been implemented, starting with a home page displaying the last documents added as well as the identity of the last care provider that accessed to the DMP. New features have been developed such as the access to images, and a button to help the patient hide some information of his/her DMP. Some screen shots of the new DMP mobile app are given in Figure 2.

4. Discussion and conclusion

After a difficult starting period, the French DMP looks to be successfully adopted by both patients and care providers. However, although the pace of DMP creation is impressive, DMP feeding is substantially increasing, and DMP consultation is beginning to happen, the DMP remains unnatural for many care providers that consider it as an extra tool on top of their usual EHR. Thus, new features are currently under development to make DMPs attractive, such as a chapter to represent the vaccination record, and the connection with mobile devices to collect relevant medical data, but it is not clear whether this will be enough and patients who are active supporters of the DMP program have to ask their care providers to populate and consult their DMP.

The next step will be the switch from the opt-in to the opt-out model where DMPs will be automatically created unless the patient opposed to it. This has been written in the last French Health Law (2019) and should be performed by the beginning of 2022.

This is similar to what happened in Australia with “My Health Record” and it is when the program started to encounter serious difficulties [7] because of public distrust over data privacy. We hope the transition to be smoother in France and expect about 60 million DMPs by 2022 (to account for the usual 10% of opt out rate). At this time, we would know if we really made it.

User Requirements Meet Large-Scale EHR Suites: Norwegian Preparations for Epic

Gunnar ELLINGSEN^{a,1} and Morten HERTZUM^b

^a *UIT – The Arctic University of Norway, Tromsø, Norway*

^b *University of Copenhagen, Copenhagen, Denmark*

Abstract. Electronic health records (EHRs) are becoming the norm in healthcare. Typically, these EHRs are large-scale suite systems. The up-front presence of ready-for-use EHR suites changes the role of user requirements and the conditions for deciding which requirements to include in the final contract. In this paper, we investigate how user requirements are negotiated in the ongoing preparations for the implementation of Epic throughout the region of Central Norway. User requirements shape vendor selection but they are also shaped by the vendors' existing EHRs and by the requirements of the selected vendor's other customers.

Keywords. Electronic health record, Epic, implementation, user requirements

1. Introduction

Electronic health records (EHRs) are becoming the norm in modern healthcare. Typically, these EHRs are large-scale suite systems with many modules and extensive configuration facilities [1]. Examples include Cerner, Epic, and InterSystems. In the initial procurement phase healthcare organizations choose among vendors that already have EHR suites ready for deployment. Subsequently, healthcare organizations negotiate configurations, extensions, and revisions with selected vendors. The initial presence of ready-for-use EHR suites changes the role of user requirements and the conditions for deciding which requirements to include in the final contract [2]. We investigate how user requirements are negotiated in the ongoing preparations for the implementation of Epic throughout the region of Central Norway. The new EHR in Central Norway is not restricted to its hospitals but will also cover its municipal healthcare services, that is, general practitioners (GPs), home care, and nursing homes. Due to the heterogeneity of these healthcare providers, the user requirements are many and diverse. It is essential to convey these requirements to the vendors. After a single vendor has been selected it is especially important that this vendor comes to understand the requirements. At the same time the requirements – and the implementation preparations in general – will be strongly shaped by the EHR suite already available from the vendor. The outcome of this process is still open [3].

We ask: *How are user requirements negotiated and shaped in the meeting with large-scale EHR suites?* Empirically, we ask this research question in relation to the Epic implementation in Norway, but the process is not specific to the Norwegian case.

2. Method

The study takes an interpretive research approach [4,5]. The data consist of interviews and publicly available documents. We conducted six interviews with top management in the Health Platform program, which is responsible for the Epic implementation in Central Norway. The director of the program was interviewed twice. The interviews were audio-recorded and transcribed for analysis. Media coverage and informal discussions with project members provided supplementary input. The data were collected in the autumn of 2018, about half a year before the contract with Epic was signed.

3. Case

The Health Platform is a regional program owned by the Central Norway Regional Health Authority and Trondheim municipality. It aims to acquire and implement an EHR for the whole region, including all the hospitals, GPs, nursing homes, and home-care services. By including the municipalities, the health authorities want to make the Health Platform a pilot for the long-term national goal of establishing a nationwide EHR functionality, "one citizen - one record" [6].

The Central Norway region includes 44,000 healthcare professionals and an approximate population of 720,000 citizens. There are 3 hospitals whereof the largest is the university hospital, St Olav's Hospital, located in Trondheim. St Olav's Hospital is already at a high level of digitization. In contrast, the level of digitization varies substantially across the GPs, nursing homes, and home-care services, where particularly the GPs already have well-working systems at their disposal. The Health Platform has identified 80 current information systems that will be replaced by the new EHR. In addition, 160 integrations between the EHR and other systems must be developed. Trondheim municipality will be in the first wave of implementation, while the rest of the 84 municipalities in Central Norway have the option to opt in after that.

3.1 *The bid for tender*

The invitation to tender was announced in August 2016 with an upper limit for the contract of NOK 2.7 billion (EUR 270 million), including licenses, the vendor's services, and 10 years of maintenance [7]. The time schedule for the main activities was as follows: vendor prequalification in 2016, dialog phase with selected vendors in 2017/2018, contract with a specific vendor signed in 2019, and implementation and go-live in 2021.

From early on, extensive user participation was identified as crucial to the success of the program. When the acquisition process started, 400 clinicians from municipalities and hospitals across the Central Norway region became involved. These clinicians participated in 101 workshops in which they described what they valued about their current information systems, what challenges they currently experienced, and what was missing. The outcome of these workshops became the basis for the requirements specification, which amounted to 4000 user requirements.

A total of 11 EHR vendors applied for prequalification in 2016. In February 2017, the Health Platform sent out the final information for the procurement of the future HER

to the five prequalified EHR vendors: Cerner, CSC Scandihealth (later renamed to DXC Technology), Epic, InterSystems, and Tieto. The tender was based on the user requirements and a dialogue with the vendors about how they planned to meet these requirements. The bids submitted by the vendors were evaluated by project members and by people from the line organization. In May 2017 four EHR vendors submitted revised bids, and in January 2018 the number of vendors was reduced to two, namely Cerner and Epic. However, Cerner decided to withdraw, because they could not see a business case for making a bid that met all requirements in the functionality for the municipalities. The contract between the Health Platform and Epic was signed in March 2019.

3.2 Negotiating the development of functionality

In spite of the substantial functionality and configurability of Epic, some new software development was needed, particularly to extend Epic with additional functionality for the municipalities. The Health Platform requested that Epic developed a pregnancy record, a medication module for home care, and support for patient-related administrative procedures such as which benefits the patient shall receive. Although Epic initially responded positively to these requests, things became more complicated closer to the deadline for signing the contract. The Health Platform had to work hard to convey Norwegian routines to Epic, particularly in relation to the administrative procedures.

A lot of functionality is dependent on integrations between Epic and other systems. In the municipalities, the systems that need to be integrated with Epic include Transmed at the security centers, employee administrative systems, economy systems, and the roster module in the administrative resource management system. The need for integration invoked questions about the location of certain data and functions. For example, the GPs' current EHR stores their economy data. As a result, all claims against, for example, the Norwegian Labor and Welfare Administration are handled in their EHR. In addition, the GPs have billing systems where patients pay for their GP visit. The vendors of the billing systems handle debt collection from patients who have not paid what they owe according to the data in the GPs' EHR. Epic was not familiar with such a setup, but with one in which the billing system handled all economy data. It requires considerable work to develop the integration between Epic and the billing systems.

To ensure the continued evolution of the EHR after its implementation, the Health Platform management envisions to increase its collaboration with other European Epic customers. This is in line with the Epic strategy for development. As a means to establish common requirements, Epic encourages its customers to collaborate on requirements for new functionality. For example, there is currently a collaboration between Epic customers in Switzerland and Denmark about the development of functionality for medication management. These collaborations mean that new Norwegian user requirements will have to be brought into alignment with those of other customers as well as to be negotiated with Epic. A new version of the entire Epic system is rolled out to all customers four times a year; the philosophy is that all new developments are available to all customers.

3.3 Configuring the system

Overall, the Health Platform management was satisfied with the configuration facilities in the system. The Health Platform was, for example, pleasantly surprised when they

learned that Partogram (graphical maternal and fetal data) functionality could be configured and, thus, did not have to be developed from scratch by Epic. However, Epic promoted configuration proactively, and sometimes at the expense of development. An illustrative example is the Health Platform's request for offline EHR functionality in the ambulances. When ambulance personnel lose online contact with the EHR, they should still be able to read and update the EHR in an offline mode, and these updates should then be synchronized with the online version later. Epic argued that the development of offline functionality would delay the project. As an alternative, they suggested that they could configure the existing user interface of the ambulance module in a way that would partially cover the requested functionality. After conferring with the relevant clinical disciplines, the Health Platform decided to let go of offline functionality and settle for the solution that Epic offered.

Configuring the Epic system in the start-up phase involves lots of decisions about how the system should function. While Epic can be configured differently for different settings (e.g., GPs, home-care services, hospitals, and nursing homes), a great deal of standardization of work processes is necessary to achieve the goal of an all-compassing EHR that can support inter-organizational information exchange and workflows. Standardization can also be a means of getting rid of unwanted variation in treatment and care. For a given patient condition and a given step in, say, an outpatient work process, the system could for example enforce the prescription of certain drugs or tests, and in a specific order. The Health Platform has established an extensive formal decision structure to decide on such standardizations, but some decisions will also require top-level approval because the standardization has far-reaching organizational consequences. For example, the Health Platform is considering to enforce a fully electronic medication management process (ordering, dispatching, distribution, dispensing, and administration), which currently is only supported by paper-based routines.

The formal decision structure will be pertinent to a successful implementation. During the preparations for going live in 2021, it is estimated that Epic will raise something like 8000-12000 questions about the details of how the system should be configured. The customer must respond within a 10-day deadline, otherwise Epic will choose the default configuration for the area in question.

After Epic has been implemented, key users (and not the vendor) will be responsible for the continued configuration of the system. In Epic terminology, these clinicians are called "physician builders". They will become responsible for configuring the layout of the system, its information flows, and its support of workflows. During the configuration of the initial Epic setup the physician builders will work together with Epic personnel. In a subsequent regional organization, the physician builders will continue to work on optimizing and streamlining work processes. To prepare for this task, the physician builders will attend a training course of up to six weeks and will subsequently work full-time as physician builders in Central Norway. This policy is intended to ensure flexibility for the users and to reduce dependence on the vendor.

4. Concluding discussion

In the initial procurement phase of EHR suites, the customer has the option of choosing between different vendors based on a detailed requirement specification. The vendors present what functionality they offer, and the development of new functionality is

negotiated. In this phase, the vendors must be able to respond satisfactorily to the customer's demands. However, after the vendor selection the preparations for implementing the system are strongly shaped by the product already available from the vendor, including its configuration possibilities. During these preparations the customer's (and future users') involvement consists to a large extent of responding to opportunities provided by the vendor, such as to queries about configuration choices. In this process the requirements specification may face considerable competition and initial requirements may be revised on the basis of descriptions and demonstrations of the vendor's suite system [8]. We are not claiming that requirements specification is no longer important but that its main role is in vendor selection.

After go-live the vendor will most likely be less available, both for system development and for configuration. New functionality that requires development must be aligned with other Epic customers along the lines of the current collaboration between Switzerland and Denmark. By encouraging such collaborations, the vendor shifts it onto its customers to reach agreement about how the system should evolve [9]. This way alliances and shared – or conflicting – interests among the customers will shape the user requirements that the Health Platform can present to Epic. Requirements specific to single customers will likely receive low priority from Epic or be considered topics for configuration (by the individual customer) rather than development (by Epic).

Regarding future configuration, it is expected that the physician builders do this. However, given that many decisions about configuration will have to be made before go-live, it is an open question to what extent it will be practically possible for the physician builders to make larger configurations later. After all, some of these decisions must be made in a complex decision structure, sometimes requiring top-level organizational approval. For larger configurations to happen, a continued organizational commitment to the same extent as in the implementation phase will probably be necessary. Without such a continued commitment, the extensive configuration possibilities will remain a dull instrument for meeting emergent user requirements.

Abstract. The purpose of this study was to investigate the value mechanisms in implementing a digital health intervention (DHI) in different contexts and countries. We utilized realist evaluation and the CIMO logic (Context, Intervention, Mechanism, Outcome) to analyze the mechanisms explaining the value capture of Klinik Pro, an Intelligent Patient Flow Management system (IPFM), which is a DHI for seeking of treatment and triage purposes. The study was conducted as a multiple case study using semi-structured interviews to research four market expansions in three countries. In total, seven healthcare mechanisms were discovered: co-creation, proper competence level, coordination, evidence-based medicine, integration, proper timing, demand management. The first four mechanisms were the same in all cases. CIMO framework proved to be useful in the value formulation of the IPFM.

Keywords. Digital Health Intervention, Value-Based Healthcare, CIMO

1. Introduction

There are increasing investments into digital health interventions (DHIs), but the value capture of these solutions is difficult to measure due to the complexity of the interventions and their implementation areas [1-2]. In particular, the mechanisms through which the outcomes of the DHI are achieved are often elusive, because there is insufficient understanding of the dynamics between the implementation context and the activated value mechanisms in healthcare. Thus, this study focuses on expanding knowledge on how to discover the mechanisms that explain the value formulation of DHIs. The approach used for this is the CIMO logic, which stands for Context, Intervention, Mechanism, and Outcome [3]. As an approach emerging from design science, CIMO can be used to structure the logic of outcomes and dynamics of an intervention when implemented in a given context [4]. Value in healthcare in this study is understood as the health outcomes achieved per resources used, i.e. a relation [5].

The studied DHI in this research was an Artificial Intelligence based intervention by a Finnish health technology company, Klinik Healthcare Solutions Oy. Their DHI,

¹ Corresponding Author: Henni Tenhunen, Aalto University, Espoo, Finland; E-mail: henni.tenhunen@aalto.fi

called Klinik Pro, is an Intelligent Patient Flow Management system (IPFM) that supports efficient seeking of treatment and triage. Patients report their symptoms online to the IPFM, which then utilizes AI to analyze the level of urgency and suggesting an initial differential of diagnoses. This information is then directed to healthcare professionals to perform further actions (Figure 1).

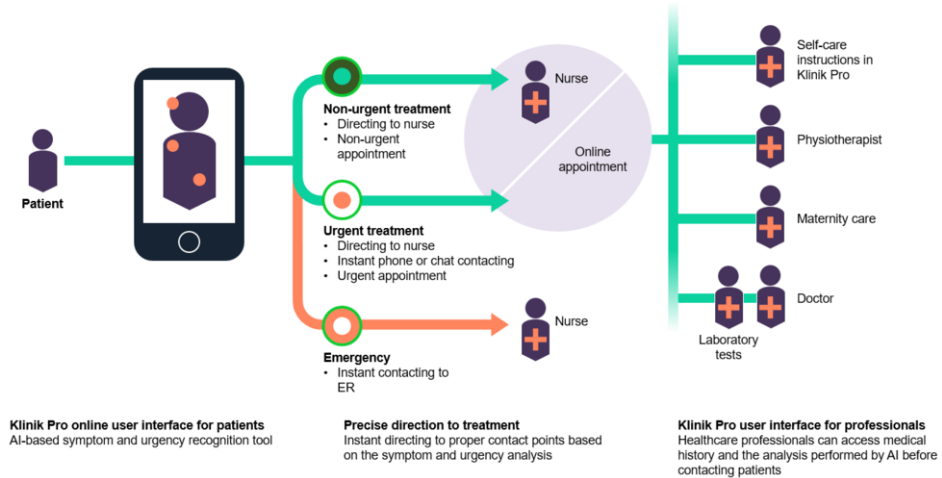

Figure 1. An example of a setup and functionalities of Klinik Pro (the IPFM)

The real-time empirical setting of this study was formed when in 2019 the company was simultaneously expanding its operations in four instances enabling international comparisons: one in Mexico, one in Portugal and two in Finland. These four contexts were analyzed using the CIMO logic and following [6]. By collecting data regarding the intervention, contextual environments, and expected outcomes of the IPFM, our aim was to deduce which value mechanisms are activated in the implementation of the IPFM. The main research question was: **RQ1: How to discover the mechanisms through which digital health intervention accomplishes value?** As a sub question we asked: **RQ1.1: How does the implementation context modify the activation of the mechanisms?**

2. Data and Methods

The research design followed the principles of design science and service engineering. Due to utilizing the CIMO logic in our empirical cases, the study also followed the principles of theory elaboration model [7] as well as grounded theory [8]. The study was performed as a multiple case study with one unit of analysis: the seeking of treatment and triage process within the primary care unit in each case (Table 1).

Table 1. Case descriptions.

Context	Targeted healthcare system	Main example of IPFM’s expected outcomes	Market phase
Large city in Finland	Public primary care	Reduce nurses’ stress levels	In Production
National association in Finland	Public primary care	More efficient handling of patient flows	Piloting / Pre-production
Large city in Mexico	Public and private primary care	Create a system to manage electronic health records	Pre-market

Medium large city in Portugal	Public primary care	Create a digital triage system	Piloting
-------------------------------	---------------------	--------------------------------	----------

We gathered data by conducting ten semi-structured interviews following the structure of the CIMO-configuration. The interviews took place during spring 2019 and were targeted on a diverse group of stakeholders within each market expansion including healthcare professionals, investors, managers, and IT experts (Table 2).

Table 2. List of informants.

Organization type	Description of the organization	Informant role
Health technology company	Klinik Healthcare Solutions	Chief Medical Officer
Primary care unit	Finnish medical center	Chief Physician
Primary care unit	Finnish medical center	Assistant Head Nurse
Primary care unit	Portuguese medical center	Managing Physician
Primary care unit	Portuguese medical center	Physician Intern
Primary care unit	Finnish medical center	Manager of Health Services
Primary care unit	Finnish medical center	ICT Service Coordinator
Venture capital	Healthcare VC company	CEO
Primary care unit	National healthcare association	CIO
Primary care unit	Mexican medical center	MD, CEO

3. Results

The activation of healthcare mechanisms relies not only on the dynamics of the intervention and its implementation, but also on the prerequisites of purposeful action. In all cases the informants considered the IPFM to improve the precision of information, break time and location boundaries, and enable inexpensive data collection from patients. However, there were differences in implementations as in Mexico the existing IT infrastructure could hinder proper use of the IPFM, whereas in Portugal the informants considered the decentralization of patient information to cause challenges. Considering the prerequisites for purposeful action, all informants considered the IPFM to provide improvements in the control information among healthcare professionals to make decisions that are more justified. Furthermore, the motivation to use the IPFM was perceived to be good in all cases. Finally, a few informants considered the IPFM to create new capabilities such as inventing new ways to plan clinical pathways utilizing the analysis performed by the IPFM’s AI.

Four healthcare mechanisms were discovered in all cases. First, *co-creation* is a mechanism that is inherently active in the IPFM due to engaging both patients and healthcare professionals in using the IPFM. Second, all informants perceived the IPFM to activate the *proper competence level* mechanism that allows the utilization of the lowest sufficient resource in each operation leading ultimately to cost savings. Third, the IPFM was considered to activate the *coordination* mechanism due to improved control information. Finally, as the IPFM’s AI performs the conditional analysis of the patients based on the most relevant scientific findings, the *evidence-based medicine* was the fourth mechanism active in all cases.

Besides the aforementioned four healthcare mechanisms, the Finnish informants considered the IPFM to support *integration* mechanism that results in more coherent and consistent knowledge of patients’ conditions. This was not considered active by the informants in the case of Mexico due to issues in the pre-existing IT infrastructure. Moreover, integration was also not considered to be activated in Portugal due to decentralized implementation. Besides integration, *proper timing*, a mechanism to

route and schedule patients effectively, was considered to be active in the Finnish cases. However, it was not seen activated in Mexico or Portugal due to same reasons as with integration. Finally, the seventh healthcare mechanism considered to be somewhat present in all cases was *demand management*. As the IPFM acts as an additional channel to seek treatment, all informants considered the possibility of the IPFM supporting efficient contacting of patients. However, in all cases it was also elaborated that this additional channel might result in overcapacity problems as patients might utilize multiple channels while seeking treatment. Thereby, the demand management mechanism was considered less relevant for all cases.

Generally, the mechanisms in each case were perceived to be very similar despite the contextual differences. In spite of the similarities, the varying intentions and priorities to utilize the IPFM among the stakeholders result in diverse outcomes responding to the actual problems the IPFM aims to solve. Thus, the same DHI can be used for very different purposes.

4. Discussion and Conclusions

By analyzing and comparing the cases, it is possible to discover patterns in the IPFM's functionality to understand its value formulation on a more general level. In short, the IPFM's ability to function correctly relies on the co-creation mechanisms to engage patients to report their symptoms to a digital system. Consequently, the practices regarding triage (e.g., whether it even exists) and the existing IT-infrastructure are the critical factors. Any issues with these factors result in uncertain activation of any healthcare mechanisms.

Depending on the willingness of actors, the IPFM produces a more precise understanding of the patient's condition, which forms a foundation for a better access, planning, and implementation of treatment. IPFM improves not only the knowledge of the patient and healthcare professionals but also enables optimization of resources, thus potentially leading to costs savings, enhanced productivity, and improved quality of care. Consequently, more effort can be allocated to actual patient care tasks. This is the kind of value that decision-makers appear to be looking for. Additionally, IPFM could even provide new competences for its users. However, a critical factor in realizing all the mechanisms rely on the users' adaptability and willingness to use the IPFM in the first place. Figure 2 illustrates this value formulation process of Klinik Pro (IPFM) on a general level. The purple color indicates patient while the red color refers to healthcare professionals. The IPFM and its activity is described with gray. Healthcare mechanisms are illustrated with blue while the outcomes are highlighted with green. The arrows indicate the interdependent relationships between the factors.

There are certain limitations in this research that need to be taken into account. First, this study concentrates merely on DHIs directed to triage and seeking of treatment, i.e. IPFM solutions. Second, the patients, the most important stakeholder group, were not studied, thus making patient perspective vital to study in future studies. Third, although being a multiple case study, the number of interviews in total was limited.

Despite these limitations, this study provides new insights into discovering the mechanisms of DHI value by examining the interdependent relationships between the intervention, its context, and its expected outcomes. Furthermore, this study supports the customers of the health technology companies (e.g. medical centers) to understand

the value formulation of similar DHIs as the IPFM, improving managerial decision-making. With this information, it is possible to concentrate on activities to maximize value capture while also detecting unnecessary activities.

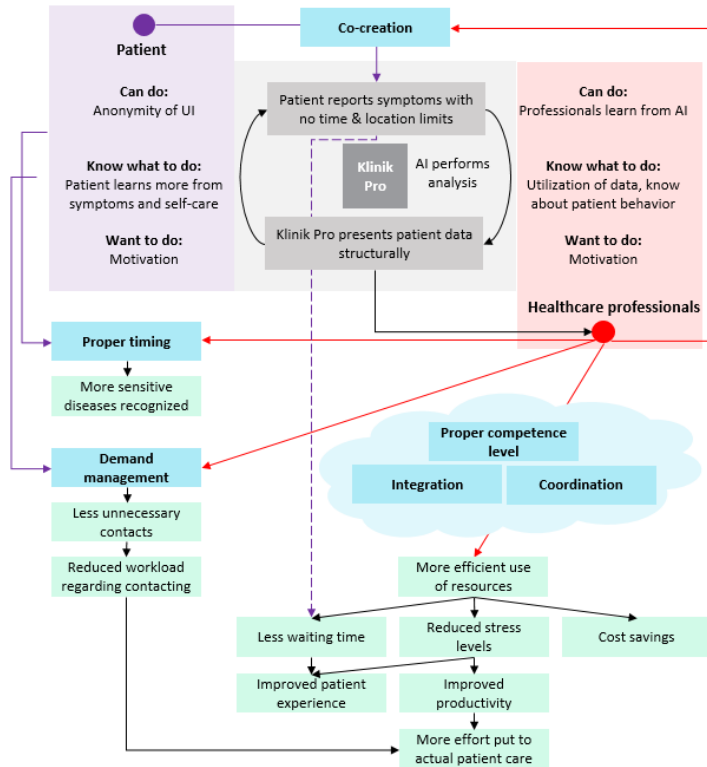

Figure 2. Value Formulation of Klinik Pro (the IPFM)

Virtual Reality Therapy for Social Phobia: A Scoping Review

Elham SALEHI^{a,1} Mahdi MEHRABI^a Farhad FATEHI^{b,c} Asiyeh SALEHI^d

^a Islamic Azad University, Shiraz, Iran

^b Centre for Online Health, The University of Queensland, QLD, Australia

^c Tehran University of Medical Sciences, Iran

^d School of Health and Human Sciences, Southern Cross University, QLD, Australia

Abstract. Virtual reality (VR) has become an interesting alternative for the treatment of social phobia. This scoping review explored the impact of VR technologies in the treatment of social phobia (25 papers were included). Treatment approaches to social phobia included virtual reality exposure therapy, cognitive behaviour therapy, exposure group therapy, in vivo exposure therapy, and waiting list. VR was identified as the most successful approach, not only in improving social phobia, but also resulting in real life changes such as improvement in occupational success. VR Head Mounted Displays were used in most of studies (76%), followed by VR-based Specific Systems (24%). Although VR techniques indicated positive impact on patients to reduce their anxiety, it is paramount to consider variables such as the way therapists control the environment as well as individuals' characteristics for achieving the best outcome.

Keywords. Social phobia, Social fear, Social anxiety, Virtual reality

1. Introduction

Anxiety disorders are characterized by apprehension, tension, nervousness, or worry. Social phobia, as the most common anxiety disorder, is the unreasonable fear of social situations and the interaction with other people that can bring on feelings of self-consciousness, judgment, evaluation, and inferiority, and can result in social isolation [1]. Diagnosis and treatment of anxiety disorders are difficult as there are no objective biomarkers, however, phobia therapy is the first-line treatment for anxiety disorders, modifying the result of fear of in-memory structures [2, 3]. The treatment approaches include Cognitive Behavioural Therapy (CBT) and Exposure Therapy (ET). CBT includes exposure to fear-triggering stimuli (e. g. speaking in front of a group), social skills training and relaxation training to change cognition and behaviours [4]. In Exposure Group Therapy (EGT), patients are exposed to the feared object or context without any danger to overcome their fears. If the patient is exposed to the real situation, it is called In Vivo Exposure Therapy (iVET) [5].

Virtual Reality (VR) is a human-computer interaction that allows a person to step into an unseen environment to face their fears which participants could react in the virtual world with their observation through images on a computer screen [6, 7, 8, 9]. VR is an effective method for the treatment of a variety of phobias such as social phobia, post-

¹ Corresponding Author: Email: eliss.salehi@gmail.com

traumatic stress disorder, claustrophobia, arachnophobia and fear of heights [10, 11,12]. This review aimed to investigate the efficacy of VR in improving social phobia.

2. Methodology and design

This scoping review systematically searched four databases (PubMed, PsycINFO, IEEE Explore, and Science Direct) from 2000 to 2018. Keywords were: ("virtual reality" OR "virtual environment" OR "cyberspace") AND ("social phobia" OR "social isolation" OR "social fear" OR "anxiety"). Peer-reviewed papers written in English that used VR for improving any case of social phobia, social fear, and social speaking fear were included. A total number of 726 records were initially considered for the review, and a final set of 25 papers were deemed eligible and included in this scoping review. Constant comparative analysis was used to explore and categorize the themes across the studies. Synthesis of the information was performed based on different approaches of VR for treating social phobia, and comparing VR with conventional treatments.

3. Results

3.1 Study characteristics

Participants' age range was 18-70. Sample size varied from 2-97, with a relatively equal distribution of both genders. Treatment included Virtual Reality Exposure Therapy (VRET) with the highest percentage (65%), cognitive behaviour therapy (CBT), exposure group therapy (EGT), in-vivo exposure therapy (iVET) and waiting list (WL). This review identified three main themes.

3.2 Virtual reality in the treatment of social phobia - trends and applications

By comparing different therapeutic approaches, VR approaches and CBT showed the most remarkable improvements in the treatment of social phobia [1, 5-6, 13-18]. There were no significant differences between VR and CBT and they indicated relatively equal outcomes [1, 6]. However, VR was highly recommended and there has been an increasing number of studies during the last 19 years. VR is affordable and provides equal or even more satisfactory results in comparison to other non-VR approaches such as CBT. VR has a paramount impact on not only the treatment of social phobia but also different aspects of personal life and wellbeing. Some examples are: more improvement in well-being and quality of life; fewer sessions for accomplishing the therapy; confidence [14], positive self-statement [5], improvement in emotion and communication, real life changes such as occupational success [7, 17], decreased fear, anxiety, avoidance of the social situation, improvement in physiological measures on public speaking anxiety, patient's attention focus, and changing behaviour [10, 14, 15].

The number of treatment sessions in VR interventions varied from 1-12 sessions and the duration ranged from 5-90 minutes. There were also variations in the follow-up period, from a few weeks to one year. Among VR approaches, iVET group was more realistic than VR conversation, and participants commented that the VR conversation would be more realistic if they did not meet the actor and if they were not in the same

room as the other participants [1, 6, 16, 19]. In addition, fear rating was higher during VR conversation than in iVET conversation [1, 6, 16, 19].

3.3. Virtual reality tools for social phobia treatment

The VR equipment can be categorized into two groups: Virtual Reality Head Mounted Displays (HMD), and Virtual Reality based Specific Systems (VRBSS). The majority of the research experiments (76%) used HMD, while, the other 24% of the studies used VRBSS, mainly different 3D display/sound equipment and motion trackers.

For HMD usage, there is a Distributed Interactive Virtual Environment, which consists of a computer, HMD, display screens for each eye, stereo ear-phones, Silicon Graphics, main memory, avatar face and model and a head-tracking system. In a virtual environment (VE), the conversation is managed through a virtual avatar interaction with participants, the virtual social situations such as shopping; attending a job interview include semi-scripted dialogues consists of modification templates based around the video game. The participants interact via HMD and wear headphones and a microphone headset to interact. Therefore, avatars mouth movements during the dialogue seem natural [19, 22, 23]. The tracker allows patients to see the virtual world with head movement in the real world, and software package that provides the scenes of speech among the audience [5, 16]. The patient's head movements change the environment, and the therapist can control the audience's reactions and communicate with them via a microphone. During the talk, their heart rate is monitored and the content of the presentation is recorded [10, 12, 14, 15, 20, 21]. Due to the limitation of VR hardware and software, and the associated expenses, off-the-shelf applications for different issues, such as public speaking practice during different scenarios have been developed and are available on mobile app stores [24, 25, 26].

VRBSS consists of the Delft Remote VR system with the capacity to display 3D video, 3D images and 3D glasses and ear headphones for sound immersion. The program displays images and then commands given by the therapist through a wireless USB keyboard for activation of the interaction and changing the scene [17, 23]. The laboratory for VRBSS comprises of two rooms that are separated by a mirror while the therapist can see the patient but the patient cannot see the therapist, they have a face-to-face contact during exposure and communicate via intercom [27].

3.4 Measurement tools in social phobia

Two types of measurements were used during the course of treatment: 1) self-report measure - individual's own report of their symptoms, behaviours, beliefs, or attitudes. This was conducted via pre-treatment and post-treatment assessments. 2) physiological measure - measuring bodily variation such as: heart rate, dry mouth, and blood pressure. An overall of 30 psychological instruments were used as outcome scales across studies [11]: APQ (answer psychology questions), ATQ30 (automatic thought questionnaire), ATPS (attitudes towards public speaking questionnaire), BDI (Beck depression inventory), BCSS (brief core schema scales), BAT (behavioural assessment task), CGI (clinical global improvement scale), DAS (dysfunctional attitude scale), DASS (depression anxiety stress scale), DSM-IV (diagnostic and statistical manual of mental disorder), EUROHISQOL (Eurohis quality of life scale), ERQ (emotion regulation questionnaire), FNE-B (fear of negative evaluation-brief Form), GPTS (green paranoid thought scales), HAD (hospital anxiety and depression), HADS (hospital anxiety and

depression scale), IPQ (I group presence questionnaire), LSAS (Liebowitz social anxiety scale), LSAS-SR (Liebowitz social anxiety scale-self report), PRCA (personal report of communication apprehension), PDBQ (personality disorder belief questionnaire), PRCS (personal report of confidence of speaker), PDBQ (personality disorder belief questionnaire), SUS (slater-Uschsted questionnaire), SCID (structured clinical interview for the DSM-IV), SSPS (positive and negative self-statement during public speaking), SCIA (social contexts inducing anxiety), SIAS (social interaction anxiety scale), SAS (social adjustment scale), SF -36 (the medical outcome 36-item short-form health survey), SSQ (simulator sickness questionnaire), SPAI (social phobia and anxiety inventory), STAI (state-trait anxiety inventory), and SUD (subjective unit of discomfort) [1-30]. Key methodological features and findings of the reviewed studies are available online ([DOI: 10.13140/RG.2.2.12587.39209/1](https://doi.org/10.13140/RG.2.2.12587.39209/1)).

4. Discussion and recommendations

VR treatment has a great impact on the communication and seems to be more effective and efficient than conventional therapies for social phobia. However, there have not been any specific comparison between different VR tools, and few mobile-base tools were considered. In addition, from a technological aspect, although HMD and VRBSS are the key effective VR tools, there has not been any specific comparison between them to examine the outcome and performance clearly.

Although the diverse variety of VR tools indicated some type of positive impact in reducing the anxiety, it is still paramount to consider confounding variables, such as the individuals' characteristics and the way therapists control the environment. Some of the participants felt anxious during VRET, due to the presence and the monitoring of the therapist during the session. In addition, therapists should try to maximize a patient's presence because attentional focus leads to better treatment. A powerful sense of presence and immersion is needed to make the experience real, and to enhance the effectiveness of the interventions [6, 21]. Further studies (with larger sample size) are required to clarify the differences between different VR tools in regards to their effectiveness and efficiency. There have been also limited studies around mobile-based VR and their potentials [24, 29, 30]. Future studies may also explore different behavioural patterns in regards to gender for using VR and the treatment outcomes.

There were issues related to the interventions that need to be considered to facilitate future studies. These include: difficulties in producing and editing movies as they are time-consuming [30]; different behavioural patterns due to gender; lack of control for audience interactions with each other for the virtual reality-based specific system; lack of sense of presence/immersion to overcome cognitive barriers [29]; and patients' anxiety due to therapist presence/monitoring [22], small sample size, and limiting the generalizability of the results of the studies [14].

^dPreemptive Medicine and Lifestyle Related Diseases Research Center, Kyoto University

Abstract. Electronic Medical Record (EMR) systems are complex systems with interdependent features. Redesigning one feature of the system can create a cascade effect affecting the other features. By calculating the cascade effect, the designers can understand how each individual feature could be affected. This understanding allows them to maximize the positive effects and avoid negative consequences of their redesign activities. To understand the cascade effect, the designers can look at their computations' results; a task that becomes more difficult when the number of features grows. To reduce their task load, we propose a tool for visualizing the cascade effect of redesigning features in an EMR system. Our preliminary evaluation with six graduate students shows that visualizing the cascade effect reduces the task load and slightly improves their performance when analyzing the cascade effect. Ways for improving the tool include (i) showing the computation results within the visualization, and (ii) allowing the designers to compare the cascade effect generated by redesigning different features.

Keywords. Design, EMR System, Visualization

1. Introduction

The designers of Electronic Medical Record (EMR) systems need to continuously redesign the systems to fulfill the emerging needs of their users [1,2]. It is common for the designers to be faced with multiple EMR features to redesign. Each EMR feature represents a distinctive aspect or attribute of the EMR system. For example, one EMR feature could be its usability, while another EMR feature could be its integration with the used medical devices. Since the designers have limited resources, they need to choose which feature to redesign. This choice is difficult because EMR systems are complex socio-technical systems where the systems' features are interdependent i.e., redesigning one feature will affect the other features of the system. For example, integrating the EMR system with the used medical devices would increase its usability. As another example, automatically generating EMR summaries from the EMR notes would facilitate the exchange of EMRs between healthcare providers which would consequently reduce the preparation time for the consultations [3].

¹ Corresponding Author: Samar Helou, E-mail: helou.samar@gmail.com.

Previous work showed that considering the interdependency of the features is needed to know which features are the most important to (re)design [3]. By calculating the cascade effect generated by (re)designing each feature, the designers can assess the overall effect that redesigning each feature will have on the system as a whole. Accordingly, the designers can optimize their design strategies by choosing to work on the features that generate the largest positive effect on the system.

To understand the cascade effect of redesigning each feature, the designers need to understand how each individual feature in the system is affected. To do so, the designers can check the details of the computations. However, when multiple features are considered, looking at the computations' outputs requires a high mental demand and could result in an incomplete understanding. In this case, visualizing the cascade effect can reduce the required mental workload by offloading work to the perceptual system [4].

The aim of this work is to support EMR designers in understanding the cascade effect of their redesign activities. To this end, we propose a tool for visualizing the cascade effect generated by redesigning features in an EMR system.

2. Methods

Previous work described a method for calculating the cascade effect of redesigning features in an EMR system [3]. First, the designers have to analyze the relationships between the features and then compute the overall effect of modifying each feature.

2.1. Analyzing the Relationships between the EMR Features

First, the designers have to analyze and quantify the influence that each feature has on all the other features. For every two features f_i and f_j , the designers have to answer the following question: "If we redesign feature f_i , how will that influence feature f_j ?"

To answer this question, the designers assume that feature f_i has a positive influence on feature f_j when an improvement of f_i leads to an improvement of f_j . Similarly, feature f_i has a negative influence on feature f_j when an improvement of f_i leads to a deterioration of f_j . To quantify the influence, the designers can employ a linear scale ranging from "-0.9: very strong negative influence" to "0.9: very strong positive influence" with the middle point being "0: no influence".

Once the relationships between the features are quantified, the designers can create the feature dependency matrix $D = [d_{ij}]$ where all principal diagonal elements are equal to zero and d_{ij} represents the degree to which feature f_i has an influence on feature f_j .

2.2. Computing the Cascade Effect

$A = [a_{ij}]$ is the direct effect matrix where a_{ij} represents the direct effect of modifying feature f_i on feature f_j . Matrix A is an identity matrix. The cascade effect of modifying each EMR feature is computed using the following equation:

$$C = A \times D + A \times D^2 + \dots + A \times D^h, h \rightarrow \infty$$

$C = [c_{ij}]$ where c_{ij} is the cascade effect that modifying feature f_i has on feature f_j .

2.3. Visualizing the Cascade Effect

The purpose of the visualization tool was to support the designers in understanding the effects of redesigning a feature. Therefore, for every feature, we needed to visualize the cascade effect that redesigning this feature will induce on all the other individual features. To build a prototype of the visualization tool, we worked with a case study of redesigning an antenatal care EMR system. We used the list of features and the dependency map presented in that study [3]. To compute the cascade effect of redesigning each feature, we used python and followed the calculation steps described in section 2.2.

We built the prototype of the visualization tool using HTML, CSS, and JavaScript. The prototype’s interface is shown in Figure 1. The green bars represent the baseline, i.e., the initial state of the EMR system before any redesign activity. By pressing on a “Redesign” button, the users can see the direct effect in blue and the indirect effects in yellow. The figure shows, as an example, the cascade effect of redesigning the EMR system to automatically generate summaries from the EMR notes. The working prototype is accessible via: casceffect.netlify.com.

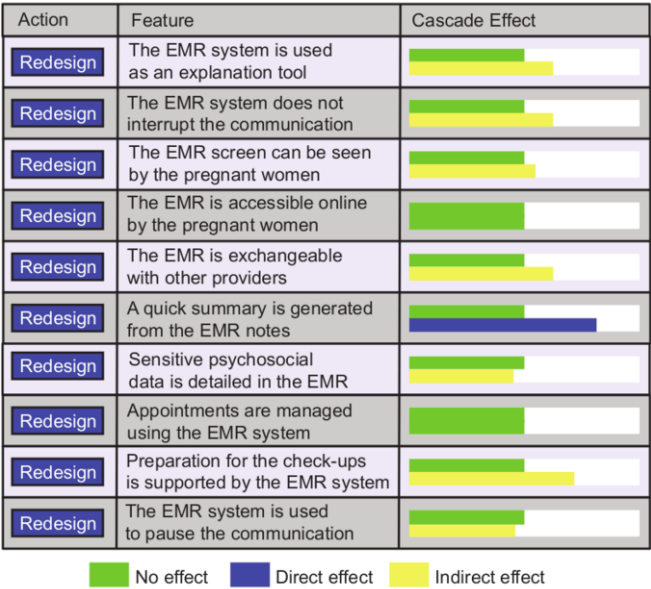

Figure 1. The interface of the visualization tool.

2.4. Evaluating the Prototype of the Visualization Tool

We conducted a preliminary evaluation of the visualization tool with six graduate students. We indicated to the participants the three features that have the largest overall effect on the system. Then, we asked them to conclude why these three features had the largest overall effect by using the results of the computations shown in Figure 2, and by using the visualization tool. Half the participants used the results of the computations first and the other half used the visualization tool first. After using each method, the participants answered a NASA-TLX questionnaire. NASA-TLX is a multi-dimensional scale used to measure the workload estimates of a task [5].

The EMR system is used as an explanation tool	1.00	0.00	0.00	0.00	0.00	0.30	0.00	0.00	0.00	0.00

Figure 2. The computations results.

3. Results

The results of the evaluation are shown in Figure 3. Each bar represents the distribution of the scores given by the six participants. By considering the mean and the median of the reported scores, we conclude that using the visualization tool tends to require less mental demand, temporal demand, and effort. Moreover, using the visualization tool may reduce the designers’ frustration and slightly increase their perceived performance. However, the tool requires more physical demand due to its interactive nature.

Figure 3. Using the computations’ results versus using the visualization tool.

4. Discussion

All the participants agreed that using the visualization tool required less mental and temporal demand than the computations’ results. However, two participants reported that the visualization tool was more physically demanding. One of these two participants further reported that using the tool required more effort and caused them more frustration. The effort required by the tool was attributed to the difficulty of

comparing the cascade effect of different features. The current prototype only allows the designers to visualize the cascade effect of one feature at a time. One way to address this issue is to allow the designers to choose multiple features and visually compare their cascade effects.

The participants also reported that they could not accurately quantify the cascade effect when they used the tool. Instead, they had to qualitatively and approximately assess it. This issue could be addressed by adding the quantitative data from the computations' results to the visualization. Moreover, in order to fully understand the cascade effect, it is important to know how the effect is propagating across the features' network. In other terms, the designers need to know the source of the effect on each feature. To this end, an animation tool showing how the cascade effect propagates along the system's features might prove fitter as these tools are usually used to represent dynamic systems [6].

Finally, it is important to note that the effect generated by a design change depends on the way the features are implemented and on the context in which the EMR system is used. Moreover, the calculated cascade effect depends on the subjective interpretations of the designers. Therefore, the prediction of the cascade effect may not accurately reflect the real world. The method's current merit lies in its ability to support the designers in finding a way of calculating, approximately, where a good course of redesign lies. Further research is needed to evaluate the method in work place settings.

5. Conclusion

Understanding the cascade effect of redesigning features in an EMR system allows designers to optimize their redesign strategies. To support the designers in their analysis, we proposed a tool to visualize the cascade effect of redesigning features of an EMR system. Our preliminary evaluation with six participants showed that the visualization tool could reduce the designers' mental and temporal demand and improve their performance when analyzing the cascade effect of redesigning the system's features. Further work is needed to reduce the physical demand required by the visualization tool and to allow designers to easily compare the cascade effect of redesigning different features.

Abstract. The paper presents a web application integrated in a platform containing hardware and software components for optimizing the activities of home care providers (HCPs) and their services. The integrated platform is called CDMS, an acronym for the Romanian translation of Dispatching and Management Center for optimizing the Services offered by HCPs. The presented web application is at the center of the platform, offering functionalities for optimizing the activities of an HCP, the activities of the nursing staff and other functionalities that will be presented in the paper.

Keywords. home care provider, web application for home care, home nursing

1. Introduction

Population aging can be defined as an increase in the proportion of older persons that changes the age composition of a population [1] and it is already well known that there is an ongoing process of aging for the population of the entire globe. Europe has the oldest population (21% of its population aged over 60).

Aging usually implies some level of decrease in physical and mental capacity and a growing risk of disease [3]. Common health problems for elders include mobility problems associated with pain and frailty, hearing/ visual acuity reduction, diabetes, depression, Alzheimer, dementia [3]. These implications are the reason that most elders benefit from continuous/ periodic care: health care and assistance in performing certain tasks.

The best motivation in developing solutions for health and social care for elders arises from studying the need (the aging population) and is driven by the altruist purpose of taking care of our elders: our older relatives. Other motivation is the fact that healthy and more independent elders can lower the burden felt on public and private health sectors and they can also contribute to the economy and the society that integrates them (by working as mentors, caregivers, innovators, entrepreneurs or other members of the workforce [3]). The less altruist reason to develop solutions for elders is the fact that a market dynamics analysis shows that older adults are projected to spend \$15 trillion annually by 2020 and they will generate more than a third of global consumption growth [4]. [4] recognizes the caregiving market as a market that offers great opportunities, as it is expected to reach \$72 billion by 2020.

The paper presents a web application integrated in a platform containing hardware and software components for optimizing the activities of home care providers (HCPs) and their services. The integrated platform is called CDMS, an acronym for the Romanian translation of Dispatching and Management Center for optimizing the Services offered by HCPs. The CDMS platform is an integrated platform containing software components: web applications acting as access portals for different types of users (a web application for users at the CDMS level and a web application for the users of HCPs: employees with different roles and permissions and patients/ informal caregivers), scripting applications for technical system administration, mobile apps for point of care documentation and supply management, APIs for integrating teleassistance/ telemonitoring devices and hardware components that allow running all the above mentioned software components. The designed functionalities for the software components are presented in [5]. The current paper focuses on the web application developed for the HCPs. The presented web application is at the center of the platform, offering functionalities for optimizing the activities of an HCP, the activities of the nursing staff and other functionalities that will be presented in the following sections. It is designed to be accessed as a Platform as a Service, so that an HCP subscribes to a CDMS and gets access to all the functionalities it needs to run.

2. Technologies used for development

Container technologies have been used to allow for a clear delimitation between data and processing and for a clear delimitation between the components dedicated to each subscribed HCPAs a security measure, the database and the web application are deployed on separate containers, to allow for better access control on the data. Another reason for using containers is for obtaining separate modules that may easily be replicated. This way, accommodating a new HCP consists, mainly, in replicating two containers: the data and the processing containers. An in-house container orchestration solution has been developed to allow the management of containers and the necessary services for each of them.

The chosen main programming language is PHP, a well-known and used programming language for web portals, for managing dynamic content, managing database connections, keeping track of opened sessions and so on. Laravel [6] is an open source development framework for PHP and it was chosen for this project. It uses the Model-View-Controller design pattern [7], it allows modular development, easy code reutilization, features that aid the testing activities, routing between the components of the web application, configuration management, template utilization, implementation of predefined security features and many other features. The database is created using MySQL, one of the most popular open source database management systems.

3. Implemented features

The web application for HCPs has been developed keeping in mind the need for integration in the whole CDMS platform.

The first step in developing the web platform consisted in analysis of the existing framework of HCPs. This stage contained documentation based on available literature

(legislation, normatives, case-studies) but also on field visits, interviews and open discussions with employees of HCPs. The specification design document summarized requests directly from the end-users.

The web application offers the following main features: management of the HCP's presentation web page; management of the HCP's service offer; employees management; clients management; inventory management; management of medical data; management of nursing visits; management of authorized devices: mobile devices for point-of-care documentation and devices for teleassistance/ telemonitoring. The web application contains predefined lists of procedures and services together with default supplies needed for each of the physiological parameters to be monitored, but it also allows for customization of these lists by allowing the input of new types of procedures and alterations on their characteristic data. A short description of the designed features is available in [5]. Table 1 presents most of the functionalities offered through the main navigation menu of the web application.

Table 1. Navigation menu (partial) of the web application for HCPs

Company configuration	
HCP profile	general information: legal name, address, logo, main contact information and other info
presentation web site	for each HCP a presentation website is generated in a predefined format: main page/ about page/ contact page/ terms and conditions for using the application
bank accounts	configuration of bank accounts used for issuing bills and other financial aspects
working addresses	configuration of working addresses
Employees' management	
manage employees list	create, view, edit employees' accounts; activate/ deactivate accounts
Patients management	
manage patients list and their electronic health records	view/ add/ edit/ deactivate patient account for each of the patients, manage: - personal data, medical record, physiological measurements, uploaded files, medical prescriptions, requested services (subscriptions), appointments
Devices management	
manage list of authorized devices	view/ add/ edit/ remove authorized devices that may access the platform (mobile devices for point of care documentation and telemonitoring/ teleassistance devices)
Supplies management	
manage list of supplies	view/ add/ edit/ remove supply item view/ add/ edit/ remove supplier view/ add/ edit/ remove producer of supplies manage current inventory inventory logs
Medical services management	
manage list of offered medical services	view/ add/ edit/ remove offered procedures view/ add/ edit/ remove managed health problems view/ add/ edit/ remove allergy types view/ add/ edit/ remove physiological parameters view/ add/ edit/ remove type of documents that may be added to a patient's electronic health record (medical report, test results, treatment plans, consent forms and others, medical prescriptions)
Subscriptions management	
manage subscriptions and offers	manage subscription types and packages of services manage offered services (other than medical)
Financial management	
manage financial documents	manage billing information/ invoices/ pricing
Calendar management	

schedule management	appointments management employees working schedule
Reports management	
generate reports	employee's activity patient's services supplies reports performance reports financial reports
Notifications management	
manage notifications for:	unpaid bills appointments: requested/ missed appointments support notifications: tickets generated by employees or patients vital parameters notifications: parameters with abnormal values supplies alerts: out of stock items or items below a predefined threshold subscriptions: expired or expiring subscriptions

These features are designed to be accessed by the following user categories: a) administrative personnel; b) nursing staff; c) clients/ patients of an HCP and their informal caregivers. These three large categories of users are identified in the activity of any HCP. In order to create an efficient (secure) access mechanism to the resources and functionalities of the web application, a role and permission based access control list has been implemented. The following roles/ activities have been identified and implemented in the platform: IT/ technical administrator; general administrator; financial manager; human resources manager; medical manager; medic; nurse; telemonitoring/ teleassistance manager. As observed from the field activities performed during the specification design phase and continued during development, different HCPs have different organizational charts, so these roles may be differently implemented in each HCP: for example an HCP may only have a small number of administrative employees, so the same person may perform multiple roles, or a larger HCP may have multiple employees for financial management so each of them must perform only a subset of the tasks involved in this specific activity. In order to accommodate that, a more specific list of permissions has been created, mainly a permission for each of the main functionality of the platform (management of the presentation web site, of the bank accounts, employees, billing and taxes, supplies, general medical data management, patients, appointments and so on). With this level of customization, a user's access to the application's data and functionalities may be accurately controlled.

4. Results

The web application has been deployed together with the other components of the CDMS platform at a center for managing HCPs in Alba County, Romania. The center is acting both as a CDMS and as an HCP. As seen in practice, the administrative personnel reported that the platform is easy-to-use, has an intuitive interface and this has been shown through the fact that it was a matter of a few months for the administrative personnel to integrate the usage of the platform in their activities. At the moment, the experimental deployment of the web application is used for keeping track of the inventory of the HCP, the employees list and test patients. Testing activities are still currently being run for each of the functionalities presented in the paper leading to functionalities improvements and minor bug fixes.

5. Conclusions and future work

The paper presents a web application for optimizing the activity of HCPs and the services they offer. The relevance of the proposed solution is increased in the context of an aging population with complex care needs that would benefit from home care services. Also, the market created for elders is expected to be the fastest growing market in the following years.

The application represents a single point of access for managing all the administrative activities of an HCP, including managing the nursing activities. There is no installation required from the point of view of an HCP. The CDMS offers the web application and the complex hardware requirements for storage and processing (in the situation of a complex HCP). The HCP only needs any kind of Internet enabled terminal to access the web application. The most important difference between the proposed solution and readily available solutions on the market, is the integration in the whole CDMS platform that offers additional components and functionalities, the most important of them include a mobile application for point-of-care documentation, a mobile app for supplies management and software components for technical management. Another important aspect of the proposed solution is the integration of an API that allows the platform to gather health data from devices provided by different vendors already on the market.

Acknowledgment

This work has been supported through the Project: Dispatching and Management Center for Optimizing Home Care Integrated Services, from Operational Competitiveness Program 2014-2020 Axis 1 – Romanian Research Ministry.

A Model for Early Identification of Chronic Obstructive Pulmonary Disease

Thomas KRONBORG ^{a,1}, Stine HANGAARD ^a, and Ole HEJLESEN ^a

^a*Department of Health Science and Technology, Aalborg University, Denmark*

Abstract. Chronic obstructive pulmonary disease (COPD) is highly underdiagnosed. Early diagnosis is, therefore, essential to reduce costs and exacerbations and prevent disease progression. This calls for the development of a COPD case-finding tool. The present study aimed to develop a model for early identification of COPD with an eye to optimizing COPD case finding. The study was based on data from the US National Health and Nutrition Examination Survey (NHANES) dataset (2007-2012). For the analysis, 772 participants with spirometry defined COPD were included. Potential predictors for COPD (n=42) were extracted. The model was based on logistic regression, and the predictors were included using a stepwise forward selection. A five-fold cross-validation was used to train and validate the model. The predictors included age, gender, and pack-years of smoking. The model obtained an AUC of 0.71. In conclusion, such a model can be useful for identifying individuals that should perform post-bronchodilator spirometry to aid early identification of COPD.

Keywords. Airflow obstruction, COPD, prediction, diagnosis

1. Introduction

Spirometry remains the decisive marker in the diagnosis of chronic obstructive pulmonary disease (COPD). According to the Global Initiative for Chronic Lung Disease (GOLD), a post-bronchodilator forced expiratory volume (FEV1) / forced vital capacity (FVC) of <0.7 confirms the presence of COPD [1]. The diagnosis of COPD should also be based on an assessment of symptoms, comorbidities, and risk of exacerbation [1]. However, COPD remains highly underdiagnosed and misdiagnosed [2–4]. Globally, approximately 70% of subjects with COPD are undiagnosed [5].

Early identification of patients with COPD is warranted. Early diagnosis may reduce healthcare costs [6], reduce exacerbations, and prevent disease progression. [2,6,7]. However, no direct evidence supports that a broad spirometry-based screening of potential COPD patients will improve longitudinal health parameters [8]. Inline herewith, GOLD does not recommend spirometry screening, and advocates for active COPD case finding as an alternative [2].

Several studies have explored the characteristics of subjects with COPD who remain undiagnosed [9–13]. One may assume that a focused model based on potential characteristics of undiagnosed COPD have the potential to improve early identification of subjects with COPD. A previous study used 34 variables based on demographic, clinical, and health care resource utilization characteristics to identify subjects with

¹ Corresponding Author. E-mail: tk1@hst.aau.dk

undiagnosed COPD [14]. However, such a model is considered too complicated for implementation. Therefore, a simple and accurate case-finding tool is yet to be developed. Thus, the present study aimed to develop a simple model for early identification of COPD.

2. Methods

Data were extracted from the US National Health and Nutrition Examination Survey (NHANES) dataset (2007-2012). NHANES data are publicly available, and they include a variety of medical, nutritional, behavioural, and demographic data. The data is collected through examinations and interviews and are representative of the US population [15,16].

Data from a total of 23,433 participants were extracted from the NHANES database. A subsample of 1,564 participants whose FEV1/FVC ratio was below the lower limit of normal or below 0.70 were asked to repeat spirometry after inhaling a β 2-adrenergic bronchodilator medication to open up their airways. Participants below the age of 40 were also removed as COPD predominantly develops hereafter, and thus 772 participants remained for further analysis.

2.1. Stratification and feature extraction

The participants were stratified into participants with COPD ($n = 460$) and without COPD ($n = 312$) based on a post-bronchodilator FEV1/FVC < 0.7. A total of 42 potential predictors for COPD were extracted involving questionnaires related to age, anxiety, BMI, chest pain, colds recently, cough, days lost to wheezing, days of recreational activity, depression, difficulty walking up ten steps, difficulty walking a quarter-mile, dyspnea, education, emphysema, exposure to exhaust fumes, mineral dust, organic dust, and other fumes, fatigue, gender, general health condition, hay fever, height, hypertension, income, lung cancer, marital status, pack-years of smoking, phlegm, race, respiratory illnesses, shortness of breath, smoked 100 cigarettes, smoking currently, smoking in household, smoking amount in household, social difficulties, trouble sleeping, vigorous work, vigorous work amount, and waist circumference.

2.2. Model training and validation

The model was based on logistic regression, and the predictors were included using a stepwise forward selection. In each step, a predictor was included if it significantly improved the model compared to the previous step ($p < 0.001$).

A five-fold cross-validation was used to train and validate the model based on the included predictors. A concatenation of the model-estimated probability of COPD for each participant was then used to form a receiver operating characteristics (ROC) curve. A ROC curve displays the true positive rate against the false-positive rate at different thresholds. The area under this curve (AUC) is used for quantifying the general performance of the model, where the AUC ranges from 0 (no correctly classified targets) to 1 (perfect classification with no false positives).

3. Results

Table 1. Predictors included based on stepwise forward selection ($p < 0.001$)

Step	Predictor	p-value	AUC
1	Age	$1.21e^{-11}$	0.62
2	Gender	$5.39e^{-8}$	0.65
3	Pack years of smoking	$2.39e^{-4}$	0.71

The included predictors involved age, gender, and pack-years of smoking, which were then used to train and validate a logistic regression model. Figure 1 presents the ROC curve based on the model’s ability to differentiate between the 722 participants with and without COPD. The model obtained an AUC of 0.71.

Figure 1. Receiver operating characteristics curve.

4. Discussion

The present study aimed to develop and validate a simple model to identify subjects with COPD. The model performance is considered acceptable as the model did not include any pulmonary function indicators. The model can, therefore, be used to identify subjects that should be considered for pulmonary function testing for early diagnosis of COPD.

The previous study by Moretz et al. [14] presented a stepwise logistic regression based on 34 variables, closely related to COPD, involving respiratory conditions, cardiovascular conditions, comorbidities, medications, hospitalizations, and patient characteristics. The model obtained an AUC of 0.75 with a sensitivity of 0.60 and specificity of 0.78. The present study presented a simple model based on age, gender, and pack-years, which is considered more likely to be successfully implemented. This model obtained an AUC of 0.71 and a sensitivity of 0.50 at a specificity of 0.78.

The present study was limited by basing COPD diagnosis solely on spirometry and not assessing symptoms, comorbidities, and risk of exacerbation.

5. Conclusion

A model approach, as described in the present study, can be used to identify individuals that should perform post-bronchodilator spirometry to aid early identification of COPD.

Abstract. Although early diagnosis of developmental delay is important, there are challenges in identifying cognitive status in developing countries because of limited human and financial resources to perform diagnostic tests. Moreover, diagnosis stability of developmental delay in children using neuropsychological tests (NPTs) can remain unsettled. The aim of this study is (1) to verify the effectiveness of a serious game (DoBrain), (2) to identify existing inconsistencies between NPTs, and (3) to explore the potential of the serious game as a complement to diagnostic tools. Eligible children who had completed results of NPTs were selected (n=119/235; 116/235; case, control). With these children's scores, we performed the Mann-Whitney U test to investigate the effectiveness of the serious game by comparing the improvement of scores in both groups. Among the participants, we additionally selected a case group to identify the potential of the serious game for detecting mild developmental delay. Using the results of the CGI-S as a baseline, we defined the participants whose scores indicated more than mild illness (≥ 2 points) in at least one area as the suspected group. The score improvement related to memory in case group was greater than that of the control group ($p < 0.05$). Furthermore, four of the NPTs were not inconsistent, and the sensitivity/specificity of DDST-II was the highest score considering CGI-S results as the ground truth (0.43; 0.96). Additionally, games measuring discrimination, velocity, memory, and spatial perception showed statistical significance ($p < 0.05$). This study verifies that the serious game can help specific cognitive areas and suggests that the serious game could be used as a low-cost and unconstrained spatiotemporal alternative to NPTs.

Keywords. Digital therapeutics, digital phenotyping, serious games, inter-observer variability

1. Introduction

Developmental delay in early childhood tends to deteriorate or spread into other psychological disorders gradually. For this reason, early detection of developmental delay at an early age is important [1]. However, conventional neuropsychological tests (NPTs) for developmental delay have two issues: the inter-observer and intra-observer variability [2] and lack of accessibility to the diagnosis of developmental delay due to cost or time demands [3]. This problem is more apparent in developing countries where access to health service is relatively difficult [4]. The purpose of this study is (1) to verify the effectiveness of a serious game, (2) to investigate the discordance of NPTs and (3) to identify the possibility of mild developmental delay in Cambodia by using a serious game.

2. Method

2.1. DoBrain and Population recruitment

This study was based on a multi-centre, two-arm, cluster-randomized controlled trial with the first endpoint to identify the effectiveness of serious mobile game (DoBrain) for cognitive development of children in Cambodia. DoBrain is a serious game based on an animated cartoon and is a smart device-based application certified for child suitability. We chose this game as an intervention tool because this app showed a high retention rate (42.5%) for 30 days compared to an 8% retention rate of general health apps [5].

In a clinical trial, we recruited a total of 403 children from Xavier School (Sisophon) and Mirero School (Phnom Penh). The participants were males and females between three and nine years old. By choosing each four classes randomly to assign into case and control group, we conducted a case-control study with a case group of 204 participants and a control group of 199 participants, which lasted from March 11 to July 31 in 2019. We assessed each group with pre-NPTs to appraise the children's overall cognitive function, executive function, memory, and attention. These included the following: (1) the clinical global impression – severity scale (CGI-S), (2) the Denver developmental screening test, second edition (DDST II), (3) the Cambridge neuropsychological test automated battery (CANTAB), and (4) the behaviour rating inventory of executive function, second edition (BRIEF-II). We guided study participants through the process of downloading, starting, and using DoBrain. Participants used provided software 2 days a week for 20 weeks. Finally, we again assessed each group using the same NPTs to measure the participants' overall cognitive function. Ethical clearance was obtained from the Ministry of Health National Ethics Committee for Health Research in Cambodia (Number: 212) before participants were recruited.

2.2. Selection of eligible users and analytic methods

Of the total 403 participants, we included those who completely underwent the four NPTs as eligible users ($n=236$). Further, we excluded the participants who did not have two pre- or post-tests (BRIEF-II, CANTAB) to evaluate the effectiveness of the serious game ($n=1$). With these participants ($n=235$), we figured out the effectiveness of this

app (Table 1) and identified the inconsistencies between NPTs (Figure 1). Furthermore, only the case group were selected to identify the potential of the serious game for detecting mild developmental delay because they had experience with DoBrain (n=119) (Table 2).

Because the line between normal and abnormal in NPTs is ambiguous, we defined suspect results of tests for developmental delay, as follows, in order to identify inconsistency between NPTs for developmental delay: (1) CGI-S: cases where a clinician with a PhD in pediatric psychology gave severity scores ranging from mild to severe (two or more points) in at least one cognitive subfield; (2) DDST-II: cases that received a caution or delay score in at least one area in each cognitive subfield; (3) CATNAB: cases with scores less than 3% on at least one sub-test; and (4) BRIEF-II: cases with at least one area with a score more than 65 converted to a t-score considered clinically significant. At this cutoff, we established a percentage to classify children as low growth, that is, less than 3% of the growth curve of normal child development. In addition, we considered the CGI-S results as a foundation for comparing the consistency of other NPTs because CGI-S is a clinician-determined measure that takes into account all available information about patients.

Finally, we conducted the Mann-Whitney U test to investigate the effectiveness of the serious game by comparing the improvement of scores in both groups (Table 1). For each test, the suspect results were visualized by binary coding: 1 for suspect and 0 for normal (Figure 1). Further, to identify the potential to classify the CGI-S results by game scores, we examined the difference of game scores in each group by performing a t-test from 1 chapter to 63 chapters (Table 2).

3. Results

Case and control groups did not show a significant difference in age and proportion of sex (their mean age is 7.0, 6.9 years, respectively; $p=0.620$; 0.613, ratio of male is 69/116 (59.5%), 71/119(59.6%)). After intervention, PRMPCI and SWMBE486 scores related to memory area were significantly improved in both groups ($p<0.05$). Furthermore, the score improvement in the case group was greater than that of the control group ($p<0.05$) (Table 1). MOTML related to attention, and psychomotor speed showed no significant difference between before and after intervention in case group ($p=0.556$).

Table 1. Comparison with pre and post-test of Case and Control group in BIREF-II test and CANTAB test

Outcomes	Case (n=119)		Control (n=116)		Median difference between groups†	p-value
	Pre test	Post test	Pre test	Post test		
BRIEF (Median, IQR)						
Emotional control	56.0 (27.0)	52.0 (13.5)	66.0 (20.5)	59.0 (21.3)	-6.0	0.025

SWMBE468 (error times)	25.0(8.5)	22.0(8.0)	24.0(6.3)	24.0(6.0)	2.5	0.010

†Estimated between-group difference (intervention –control) after the intervention (post-test), for pre-test values

The CGI-S result showed that 200 participants were classified into the normal group, and 35 participants were classified into the suspect group (85.1% and 14.9%, respectively). With these participants, inconsistencies were seen between the results of the four NPTs (Figure 1). In addition, using the results of CGI-S as a baseline, there were variabilities in the sensitivity and specificity of DDST-II, CANTAB, and BRIEF-II (sensitivity, specificity: 0.43, 0.96; 0.34, 0.67; 0.89, 0.49; respectively).

Figure 1. Inconsistency between four neuropsychological tests ([A] heatmap and [B] Venn diagram)

In the case group, chapters of DoBrain 4, 5, 22, 23 and 24, showed statistically significant differences in average game scores of the normal and the developmental delay group. In particular, the average of game scores for measuring discrimination, spatial perception and inference, organizing, memory and velocity perception areas in chapters 4, 5, 22, 23, and 24 were significantly higher than suspected group ($p<0.05$).

Table 2. Chapters in DoBrain showed statistically significant differences based on CGI-S results

	Normal Group (n=105)	Suspected group of developmental delay (n=14)	p- value
Chapter 4: Discrimination, (median (IQR))	10.5 (0.6)	9.2 (1.1)	0.048
Chapter 5: Spatial perception, (median (IQR))	7.9 (3.3)	6.9 (2.2)	0.011
Chapter 22: Inference (median,(IQR))	8.9 (2.2)	8.1 (1.3)	0.037

Chapter 23: Organizing, (median (IQR))	8.2 (1.4)	7.3 (1.3)	0.008
Chapter 24: Memory, (media, (IQR))	10.2 (1.6)	9.6 (1.4)	0.017
Chapter 24: Velocity perception, (media, (IQR))	8.2 (1.4)	7.1 (1.1)	0.006

* The number of children who played each game is slightly different for each game chapter

4. Discussion

The first major finding of this study is that this serious game can improve the memory area of children in Cambodia. To identify the effectiveness of this intervention, we adjusted the effect of the natural development process by comparing differences in scores between the case and the control group. The scores of BRIEF-2 did not change; however, BRIEF-2 is based on the scores reported by teachers, so we considered it to be the result of observer-variability in the BRIEF-II test.

Second, the conventional tests were not consistent and varied in criteria for suspected mild developmental delay, even in the same child. Although the purposes of these tests are to screen for developmental delay in children or to measure cognitive level, this inconsistency may result from measurements of heterogeneous areas. For example, BRIEF-II can measure eight cognitive areas in detail; however, DDST-II can measure only four areas.

Lastly, we found games where the average of game scores differed between the two groups related to CGI-S results. In particular, the discrimination, inference, velocity, memory and spatial perception categories within the game showed high relevance.

This study has a limitation that cognitive levels of children were over or underestimated because some children were suspected of having mild developmental delay by comparing their score to that of other children (under 3%). To make our findings more robust, further research with clear diagnosis data is needed.

In conclusion, this study verified that a serious game could help in the improvement of specific cognitive areas and showed that inconsistencies exist among four conventional NPTs. It also identified the potential for serious games to be used as a low-cost, unconstrained spatiotemporal NPT in low- and middle-income countries.

Current Use of Sensor-Based Measurements for Paraplegics: A Literature Review

Nils-Hendrik BENNING^{a,1}, Niclas HAGEN^a and Petra KNAUP^a

^a *Institute of Medical Biometry and Informatics, Heidelberg University, Germany*

Abstract. Sensors are used in many fields to measure physical phenomena, often on mobile persons. Paraplegia is a disease with a massive impact on the ability to move, so patients show changes in walking behaviour or are even wheelchair users. It is unclear how sensors can be used with paraplegics to generate valid data for research. In the ParaReg project, such data shall be integrated with a medical register. In this paper, we elaborate current approaches for sensor measurements that might serve as an additional data source for ParaReg with the help of a literature review. We queried IEEE Xplore and MEDLINE to find publications that describe the current use of sensors for patients with paraplegia. The retrieved publications were screened for eligibility by two reviewers independently. To ensure reproducibility, we conducted an initial alignment. All publications were assessed based on their abstract. Inclusions were analysed for their major topic, and we proposed categories, which were statistically described afterwards. We retrieved 685 publications in total and included 287 publications in our analysis. The categories we found are: “diagnostic sensor tools for clinical environments”, “seating position analysis”, “functional electrical stimulation (FES) / neuroprosthesis control”, “seating position analysis”, “control systems for devices” and “assessment of physical activity”. “FES / neuroprosthesis control” shows most publications and the highest publication rate in history, followed by “assessment of physical activity”.

Keywords. Sensor, paraplegia, spinal cord injury, literature review.

1. Introduction

The use of sensors to measure physical functions is an evolving field. Such measurements can be used to observe various physical phenomena or even to control technical systems [1]. One example of an observational measurement is the assessment of patient postures. Typical methods and solutions in this field are suited for healthy or mobile persons. But paraplegia is a disease which limits the physical functions of patients significantly [2]. So, these methods might not be appropriate for paraplegics because they show unwanted different walking patterns [3] or even use a wheelchair.

In the ParaReg project, we want to find out how sensor data can contribute to the database of medical registers, to enrich the medical information value. With this

¹ Corresponding Author, Nils-Hendrik Benning, Institute of Medical Biometry and Informatics, Heidelberg University, Im Neuenheimer Feld 130.3, 69120 Heidelberg, Germany; E-mail: nils.benning@med.uni-heidelberg.de.

literature review, we want to elaborate on current approaches for sensor measurements in care and research that might be used in ParaReg.

2. Methods

We systematically reviewed original works in IEEE Xplore and MEDLINE databases. Our research question for this review is: for which purpose were sensors used for patients with paraplegia. We accepted reports on experiments or other kinds of presentations, like developed prototypes or concepts. For our study, we considered articles from all years in English and German language. The search was performed on the 1st June 2019 and updated on 1st July 2019 using the following search strategy, exemplarily presented based on the PubMed query.

```

("sensor"[Title/Abstract]
 OR "sensors"[Title/Abstract]
 OR "gyroscope"[Title/Abstract] OR "gyroscopes"[Title/Abstract]
 OR "accelerometer"[Title/Abstract] OR
"accelerometers"[Title/Abstract] OR "IMU"[Title/Abstract]
 OR "inertial measurement unit"[Title/Abstract]
 OR "inertial measurement units"[Title/Abstract]
 OR "inertial sensor"[Title/Abstract] OR "inertial
sensors"[Title/Abstract] OR "GPS"[Title/Abstract] OR "Global Positioning
System"[Title/Abstract] OR "Fitness Trackers"[Mesh]
 OR "Fitness Tracker"[Title/Abstract] OR "Fitness
Trackers"[Title/Abstract] OR "Activity Tracker"[Title/Abstract] OR "Activity
Trackers"[Title/Abstract] OR "Activity Monitoring"[Title/Abstract])
AND
("Spinal Cord Injuries"[MeSH Terms] OR "SCI"[Title/Abstract]
 OR "Spinal Cord Injury"[Title/Abstract]
 OR "Spinal Cord Injuries"[Title/Abstract]
 OR "paraplegia"[MeSH Terms] OR "Paraplegia"[Title/Abstract])

```

The query consisted of two main parts, linked by an AND condition. The first part queried for sensors. The keyword “sensor” was extended by common sensor forms, which might be used instead of the general term “sensor”. They were added with OR conditions, so the query became broader and not narrower. The second part of the query was specific for the disease. Because of the ambiguous use of language, we included both paraplegia and spinal cord injuries.

The search strategy was transferred to the IEEE syntax in order to query the second database in the same manner. Besides these queries, we did not use any filters or limits.

The retrieved articles were merged into a single reference list, and then duplicates were eliminated. The screening started based on abstracts, which was done by two reviewers independently. Eligibility of an abstract was assessed on the fact if it was assignable to a type of sensor-based measurement for paraplegics. Furthermore, we used the following exclusion criteria:

- E1 – Studies not published in English or German
- E2 – Publications not related to patients with paraplegia or spinal cord injury
- E3 – Reported exclusively on animals
- E4 – Not presenting original work in the field
- E5 – Presentation of work in the field of Biochemistry

We conducted an abstract-based initial alignment with both reviewers. We measured the agreement of the decision for either “include, relevant publication” or one of the exclusion reasons (E1-E5). Afterwards, the agreement of the reviewers was assessed with Cohen Kappa; values above 0.75 were accepted [4]. Disagreement during the initial assessment was solved by an intensive discussion of the article’s abstract and on content. After the initial assessment, all remaining publications were split and each of them assigned to one reviewer. For the included publications, the reviewers began to develop categories, describing the kind of sensor-measurement in the use case. This development was done cooperatively and inductively. Each inclusion was assigned to the best fitting category. In cases where there was no appropriate category defined, the reviewers discussed different approaches before introducing a new one.

The included and categorized articles were exported to a separate table and analysed statistically.

3. Results

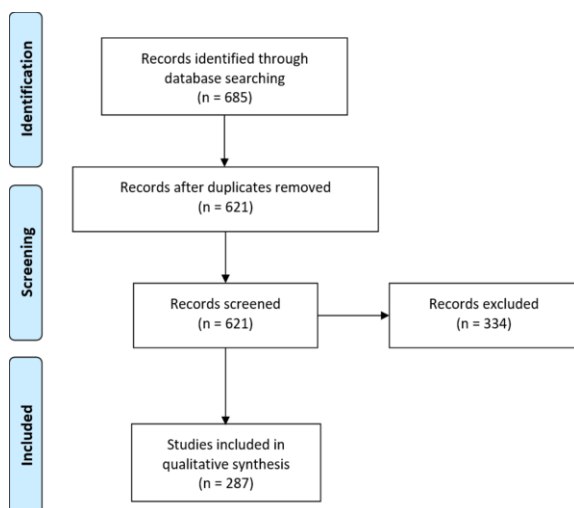

Figure 1 - Flow Chart of the screening process (adopted from [5])

In total, we retrieved 685 publications. There were 621 distinct ones without duplicates. During the initial assessment, we achieved a Cohen Kappa of ~ 0.85 , which was accepted due to the given threshold of 0.75. We excluded 334 publications during the screening. So, in total, we included and thus classified 287 publications, which can be found in the published dataset [6].

The analysis of the abstracts resulted in five categories. These categories have been assigned to the included publications. The categories and the share of publications in them are:

C1 (9,1 %) – Diagnostic sensor-based tools, which are suited only to clinical environments or study centres (non-mobile)

C2 (9,1 %) – Seating position or pressure distribution analysing in wheelchairs

C3 (50,9 %) – Control systems for FES devices (functional electrical stimulation) or other neuroprostheses

C4 (11,5 %) – Human control interfaces for devices (e.g. personal computers)

C5 (19,5 %) – Focus on the assessment of physical activity

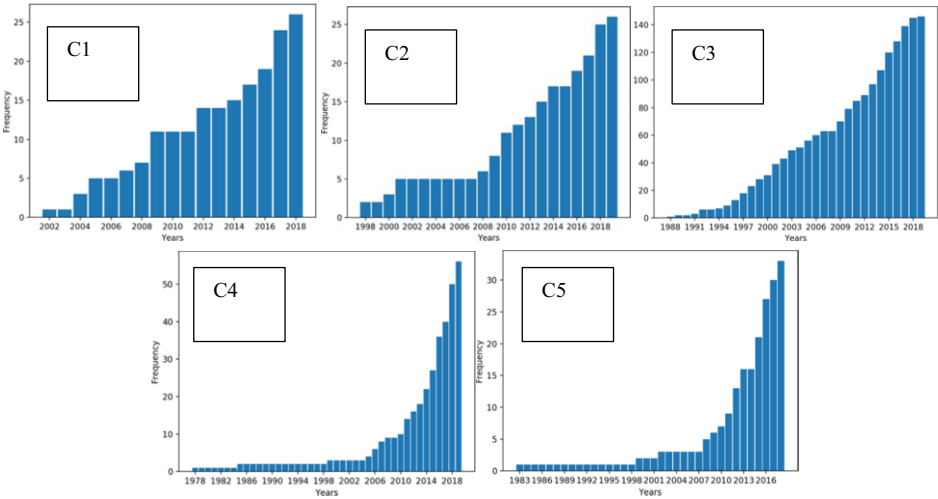

Figure 2 illustrates grafically the cumulative publication activity for the five categories.

To analyze if the found publications are also an evolving topic, with recent publications and ongoing activity, we analyzed the publication history. Figure 2 shows the cumulative publication activities. C3: “FES / neuroprosthesis control” (Figure 2) only has very few periods where no new publications appeared, and it increased rather steadily. In contrast, “assessment of physical activity” (C5) did not have new publications for 14 years in a row (see Figure 2). “Diagnostic sensors for clinical environments” (C1), “seating position/pressure analysis” (C2), “control systems for devices” (C4) and especially “assessment of physical activity” (C5) have a stronger increase in 2018. “FES / Neuroprosthesis control” (C3) shows a comparable increase in 2016/2017.

Table 1 - Total number of publications in the given topics

Measure	C1	C2	C3	C4	C5
Sum	26	26	146	33	56
Share	9.1 %	9.1 %	50.9 %	11.5 %	19.5 %

4. Discussion

All included publications could be assigned to one of the five categories. “FES / neuroprosthesis control” (C3) seems to be the field of research with the longest history and richest experience. Younger categories are “control systems for devices (such as personal computers)” (C4), “diagnostic sensors for clinical environments” (C1) and “seating position/pressure analysis” (C2).

First publications appeared remarkably close to each other in the categories “diagnostic sensors for clinical environments” (C1), “seating position/pressure analysis” (C2) and “control systems for devices” (C4) (years 1998-2002). Improved availability for sensor technology could explain this. The first publications in “FES /

neuroprosthesis control” (C3) appeared a decade earlier and continuously increased, which suggests a higher maturity of C3 compared to the other fields. First publications on “assessment of physical activity” (C5) appeared in 1978; however, there was a long stagnation of the publication counts until 2005.

The insights of this systematic review have to be interpreted with care. Even though the search strategy was very generic, the used keywords might always lead to selection bias, and thus the results cannot claim to be exhaustive. However, by using one medical database and one technically focussed database, combined with a generic search strategy, we could identify a reasonable number of relevant articles and corresponding categories.

5. Conclusions

The use of sensors for paraplegics is not new (first publications from 1978), but it is still a highly relevant topic, as publications rates are even increasing within five categories during the last years. This encourages sensor-based data generation in one of the categories found for integration into the ParaReg register, to support medical research with a more extensive database.

Detection of Psychomotor Agitation Pattern from Motion Sensor Data in a Living Environment of a Patient with Dementia

Corinna MIELKE^{a,1}, Rasmus ANTONS^a and Reinhold HAUX^a

^a*Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School, Braunschweig, GERMANY*

Abstract. Agitation is a symptom of many mental illnesses such as dementia. The aim of this work is to detect psychomotor agitation pattern in the living environment of a patient with dementia. To reach this goal, we built a smart home environment to collect the motion data of our patient. These data can be used to show the single movements of a person between different rooms in this apartment. The interpretation of these movements allows us to conclude if movements are normal or look like psychomotor agitation, in particular wandering around. This information might be useful for further analysis and interpretation. Additionally, it might be possible that the movement can give an indication of possible mood and behavioural changes in the patient. So it should be possible to create a long-term living environment that enables residents to live a long and independent life in their own home.

Keywords. Mental illnesses, dementia, behaviour monitoring and interpretation, ambient assisted living, health-enabling and ambient assisted technologies, home automation technology, smart home

1. Introduction

Agitation describes a neuropsychiatric symptom which is characterized by pathologically increased, unproductive motor activities and the feeling of being driven and agitated. [1] According to this definition, agitation manifests itself through excessive motor activities such as nesting, reaching around, constant undressing, trembling or pointless wandering. The basic characteristic of agitation is that the hyperactive movements are carried out hastily, erratically and aimlessly. In particular, this symptom can be found in mental illnesses such as dementia or depression. [1]

The review by Khan et al. [2] gives a brief overview of the existing studies that use sensors to detect agitation in patients with dementia. They conclude, “*that actigraphy shows some evidence of correlation with of agitation and [...] multi-modal sensing has not been fully evaluated for this purpose*” [2]. Therefore, the research question of this paper is, if it is possible to detect *incidences* behaviours such as aimless wandering in the home with home automation technologies and health-enabling and ambient assistive technologies (HEAAT). This question is based on the work of Haux et al. and

¹ Corresponding Author: Corinna Mielke, Peter L. Reichertz Institute for Medical Informatics (PLRI), University of Braunschweig – Institute of Technology and Hannover Medical School, Mühlenpfordtstr. 23, D-38106 Braunschweig; E-mail: corinna.mielke@plri.de.

their conclusion that “*HEAAT remain an important field for future health care and for interdisciplinary research*” [3]. In addition, Mielke et al. describe in [4] the first example of an apartment as a diagnostic and therapeutic area. Following this example, it is possible to build up several modern apartments equipped with information and communication technology for medical care. They used home automation technologies and HEAAT to build this apartment, and as a result, they presented data from various types of sensors. Therefore, our goal is to build a Smart Home for medical care with the function to detect the psychomotor agitation pattern from motion sensor data in a living environment of a patient with dementia.

2. Method

In cooperation with Baugenossenschaft Wiederaufbau eG we equipped a housing unit in a building complex of assisted living with a home automation system, which can record and analyze selected data of the resident. Our first step to build this system was to develop a technical concept and a design on how to equip the apartment with sensors and smart home technologies. We decided to use the home automation system “provedo” with flat cables to minimize expenditure and cost for retrofitting. This home automation system was built by former company PROVEDO GmbH, and retrofitting was done by Baugenossenschaft Wiederaufbau eG. We equipped the apartment with a mini-computer and the necessary software to collect and analyze home automation data. In the following, we describe some details of this home automation system, the algorithm and the graphical user interface we developed for the detection of movement agitation patterns from motion sensor data in a living environment.

2.1. Details of the home automation system – sensors, data, resident

The apartment was equipped with different sensors. The installation includes motion sensors for activity detection, power sensors to collect the energy consumption, temperature and humidity sensors for automatic control of the heating system as well as contact sensors to detect the opening and closing of windows and doors. Therefore, the resident can experience several comfort functions like an automatic heating system, a chip-controlled door lock for keyless opening, a floor lighting as a night light, a stove and window control display and a stove monitoring. Additional to these comfort functions, the data collection runs autonomous and without any intervention of the resident. The sensors we used in the system are not intrusive and inconspicuous. PROVEDO offered a house bus system (see figure 1), which could easily be installed in existing apartments. Flat ribbon cables were used which could be placed under the wallpaper. The sensors and actuators are small devices that were mounted on the wall or ceiling like a light switch or smoke detector and thus could be integrated inconspicuously into the entire electrical installation of the home. Figure 1 shows the positions of the sensors in the apartment. The data recorded by the sensors are movement data within the apartment, the power consumption of the apartment, power consumption of the stove, room temperature and humidity, window status (open/closed) and access control. For the detection of psychomotor agitation, we used data recorded in the retrofitted apartment by a male subject aged 85+ and diagnosed with dementia between October 2016 and October 2018. The subject’s guardian was

informed about the project details and a signed consent form for the collection and use of data is available.

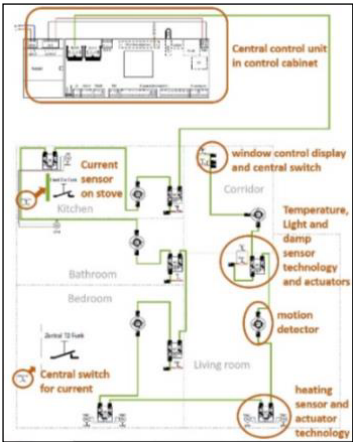

Figure 1. Schematic for the installation of sensors in the apartment with designation of individual components.

2.2. Algorithms for detection of movement agitation pattern

A relevant evaluation related to the behaviour of a person is the detection of inner restlessness and agitation. This evaluation is possible with the help of the analysis of all movement events over a certain period. In doing so, coherent movement sequences are identified, documented and evaluated. Connected motion sequences result from observation of individual motion events between rooms and their temporal distances. These movement sequences can be observed, recorded and evaluated by monitoring movements through individual rooms of the subject's home. In particular, the duration of an agitation phase and the frequency of room changes are of interest.

Motion sensors on the ceiling of each room are the basis for movement detection. They generate an event every time they detect motion, which is stored as the number of events per second. We only attempt to detect movements when one person is present in the apartment. The first step is to create a list of the resident's location for every time of day. Because the detection radius of sensors in neighbouring rooms overlap, it is possible to detect one person as being present in two rooms simultaneously. When no sensor detects motion, the resident has either left the residence or is rather motionless in the current room. We assume the resident has left the apartment if no motion is detected for 30 minutes, and the last room was the corridor. The following list with the current timestamp and the corresponding room in the residence can be derived from the data.

```
[ [1498953600000, ["bathroom"]],
  [1498953955000, ["bathroom", "corridor"]],
  [1498954003000, ["corridor"]],
  [1498954037000, ["living room"]],
  [1498954044000, ["living room", "bedroom"]],
  [1498954091000, ["bedroom"]],
  ...]
```

The list of all movement sequences is composed of individual movements, which are aggregated to a complete sequence if on the last individual movement the occupant stays at the same place for at least three minutes. A sequence of movements is marked

as critical if it lasts more than three seconds and contains the same room more than three times none consecutively. It is also marked critical if it contains impossible room changes, i.e. a direct change between two non-neighbouring rooms because this could indicate that more than one person is present.

3. Results

The data analysis results in a list of movement sequences. Due to its type and quantity of information contained, this list is now the basis for assessment and evaluation of individual movement sequences with regard to inner restlessness and agitation. For the research apartment, figure 2 shows the general overview of the evaluation for the movement data. The schematic floor plan with the possible movement points for orientation and better visual comprehensibility of movement sequences in the apartment is shown. The selected period is also displayed as well as the general summary for all found motion sequences and the motion sequences that were marked as critical through the evaluation for inner restlessness. In addition, this illustration also shows a normal motion sequence from September 26, 2017, with a defined start and end of the motion and the list with single movement sequences detected in the selected period. The motion sequences of this list that are marked as critical in the sense of inner restlessness are shown in red. Figure 2 shows a passage to the bathroom with a duration of 1 minute and 16 seconds.

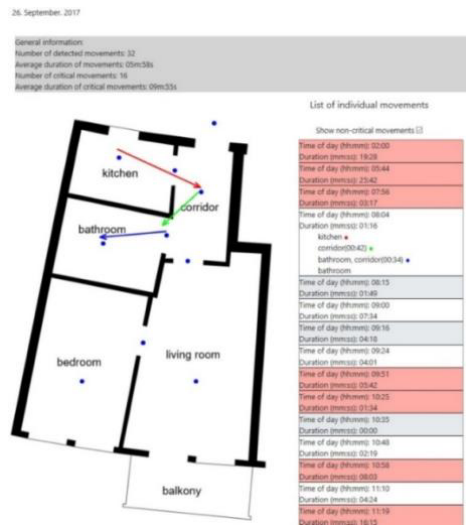

Figure 2. Controlled and targeted movement - a normal motion sequence with a defined start and end (Example from September 26, 2017, blue dots - motion points for single and neighbouring rooms, a motion is marked with an arrow in the floor plan and the same colour dot in the list of motions).

In contrast, figure 3 shows an accumulation of movement on the same day that has been evaluated as critical or conspicuous. This motion sequence is characterized as critical because each stay per room has lasted less than three minutes and contains the same room more than three times none consecutively.

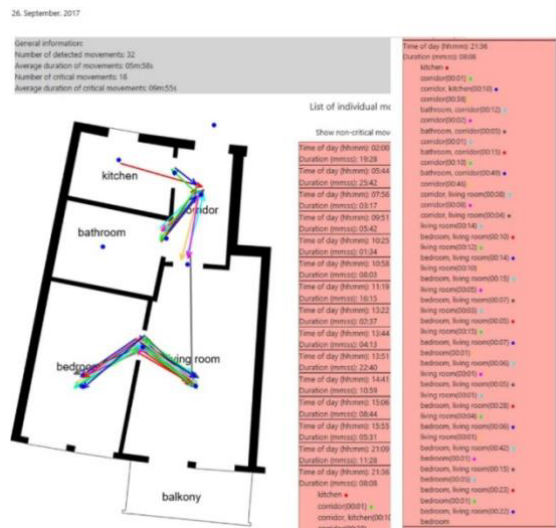

Figure 3. Agitation movement – movement sequence with many room changes about a duration of 8 minutes (Example from September 26, 2017, blue dots - motion points for single and neighbouring rooms, a motion is marked with an arrow in the floor plan and the same colour dot in the list of motions).

4. Discussion

The movement sequences marked as conspicuous or critical can give an indication of possible changes. The accumulation or temporal shift of such movement sequences could be indicators of a changing state of health in patients with dementia.

With the knowledge gained from this, we can develop systems that detect changes in lifestyle at an early stage. This enables relatives, caregivers or -providers, and doctors to intervene in a supportive manner in time. Thus, it should be possible to create a long-term living environment that enables residents to live a long and independent life in their own homes. In future work, we want to refine the algorithm, so that it is possible to improve the statements regarding agitations. Furthermore, we consider how a suitable study plan could look like in order to investigate to what extent agitation episodes can possibly be reduced with the help of the developed algorithm.

ECG-Quality Assessment of Dry-Electrode Cooperative Sensors

Michael RAPIN^a, Josias WACKER^a, Damien FERRARIO^a, Etienne HAENNI^a,
Stephan DASEN^a, and Olivier CHÉHELAT^{a,1}

^a CSEM SA, Neuchâtel, Switzerland

Abstract. Classical approaches for measuring high-quality ECG require the use of gel electrodes and individually shielded cables, which limit patient comfort, especially in long-term use. We recently introduced a novel sensing architecture—so-called cooperative sensors—that allow the use of active dry electrodes connected by two unshielded wires. The aim of this work is to qualitatively evaluate an ECG recorded with a dry-electrode cooperative-sensor system. To that end, preliminary observations were made on three healthy subjects. The ECGs were concurrently recorded with cooperative sensors and a gold-standard 12-lead ECG device during a stress test on a stationary bicycle. First experimental measurements demonstrated the reliability of the approach for a wearable 12-lead ECG monitoring system tested in real settings.

Keywords. Wearable sensors, dry electrodes, electrocardiography (ECG), multi-lead, active electrodes, cooperative sensors, long term monitoring.

1. Introduction

For many years the electrical activity of the heart has been measured with adhesive gel electrodes connected with shielded cables to a centralized electronic device used to record the electrocardiogram (ECG) signals [1]. One of the limitations that blocked the market entry of alternative wearable solutions—such as textile electrodes—was their signal quality that was not demonstrated as sufficient for medical use [2]. In order to solve this issue, we developed and patented active dry electrodes called “cooperative sensors” [3]. Cooperative sensors rely on voltage-sensing analog frontends which are directly placed onto the skin, allowing to maximize the input impedance and to reduce the sensitivity of the system to electromagnetic disturbances [4]. In addition to replacing glued gel electrodes with more comfortable, glue-free dry electrodes, cooperative sensors do not need shielded cables but work with a non-shielded two-wire bus which makes their integration in a garment simpler and further increases the wearing comfort of the system.

Since cooperative sensors use a different transducer (dry instead of gel electrodes) and a different way of application (pressure from a tight-fitting vest instead of an adhesive), tests cannot be limited to compliance to medical standards (e.g., IEC60601-2-47 or IEC60601-2-25), but require a qualitative assessment in a real setting. This work presents such an assessment.

¹ Olivier Chételat, Corresponding author, CSEM, Rue Jaquet-Droz 1, 2000 Neuchâtel, Switzerland; E-mail: olivier.chetelat@csem.ch.

2. Methods

The prototype depicted in Fig. 1 uses ten cooperative sensors embedded in a vest to measure 12 ECG leads [5]. The cabling, connecting the sensors together, consists of a bus of two non-shielded wires integrated into the textile of the vest. Sensors are located according to the Mason-Likar placement [6]. They are attached to the vest and connected to the two-wire bus with snap buttons. All sensors have a stainless-steel dry electrode. The diameter of each electrode in contact with the skin is 28 mm. To start a recording, the vest is simply put on naked skin (neither skin preparation, nor shaving) and closed with the zipper. The sensors automatically start to measure the ECG leads when they get in contact with the skin. One of the sensors (the master sensor) collects the ECG signals and sends them via Bluetooth to an external unit (e.g., a computer or a tablet), where the data is displayed and recorded for further analysis. As shown in Fig 1, ECG lead II is also displayed as a continuous wave below the 12-lead complexes.

Figure 1. 12-lead ECG system under test made of ten dry-electrode cooperative sensors embedded in a tight-fitting vest [5].

The ECG-quality assessment was performed on three healthy male subjects. The clinical standard 12-lead ECG System Cardiovit CS-200 (Schiller, Baar, Switzerland) was used as a reference. The gel electrodes of the reference system were glued onto the skin at locations as close as possible to those of cooperative sensors (see measurement setup shown in Fig. 2). The subjects underwent the following three-steps protocol: 1) a few minutes resting in supine position; 2) exercise stress test on a stationary bicycle (starting at 50 W, increasing the intensity in 25 W-steps, each one 2 min long, and up to the subject's capability); 3) recovery in supine position.

Figure 2. Test setup with reference system (left) and subject performing the ECG stress test (right).

3. Results

Fig. 3 shows excerpts of signals recorded on subject 1 with the reference system (black curves) and with the dry-electrode cooperative sensors (red curves) before (left) and during (right) the stress test. The ECG curves in Fig. 3 exemplify the general qualitative observation that the signals acquired from the two systems are very similar. As shown in the right graph in Fig. 3, similar noise appears simultaneously on both signals, which means that the electrical artefact is already present on the body. Differences in the shape of the signals (see for example Fig. 4, which shows a ventricular ectopic beat in the lead II and lead V2) are best explained with the position of the electrodes that cannot be exactly the same for the reference system and cooperative sensors.

Figure 3. Typical ECG measured on the first subject with the reference system (black) and dry-electrode cooperative sensors (red): (left) supine position at rest before stress test and (right) during the stress test.

Fig. 5 shows that the baseline wandering is similar for both systems. However, the baseline of the data acquired with the Cardiovit CS-200 may be improved via signal processing with their baseline stabilizer that reduces baseline fluctuations. However, the purpose of this evaluation is not to compare the signal quality after post-processing but to qualitatively compare the ECG acquires with both systems that have an equivalent bandwidth.

Qualitative observation on Fig. 6 shows that ECG signals acquired from both systems on the second (left) and third (right) subjects during the exercise stress test are very similar. We can also notice that similar noise appears simultaneously on signals from both systems.

Figure 4. Typical ECG measured on the first subject with the reference system (black) and dry-electrode cooperative sensors (red): (left) ventricular ectopic beat seen from lead II and (right) same ventricular ectopic beat seen from lead V2.

Figure 5. Comparison of baseline wandering during motion (160 s measurement on the first subject). Cooperative sensors (red) behave slightly better (no other filter than the basic 0.05 Hz to 150 Hz first-order band-pass filter) than the reference system (black).

Figure 6. Typical ECG measured with the reference system (black) and dry-electrode cooperative sensors (red) on the second (left) and third (right) subjects during the exercise stress test.

4. Conclusion

This paper demonstrates the feasibility of measuring a 12-lead ECG with dry-electrode cooperative sensors in a real-life setting. The observations performed on three healthy subjects qualitatively shows that the dry-electrode cooperative-sensor technology provides signals—at rest and during exercise stress tests—of quality equivalent to conventional 12-lead ECG systems. Further studies must be carried out in order to formally validate these promising preliminary observations.

Gesture Classification for a Hand Controller Device Using Neural Networks

Stelian NICOLA^{a,1}, Oana Sorina CHIRILA^a and Lacramioara STOICU-TIVADAR^a

^a*Department of Automation and Applied Informatics, University of Politehnica Timisoara, Romania*

Abstract. This paper presents a convolutional neural network-based classification of the hand flexion and extension gestures used in wrist recovery after injury. The hand gesture recognition device used in our study is the Leap Motion controller. The Leap Motion device's inability to accurately differentiate the left hand from the right hand when performing hand rotation gestures was eliminated by introducing hand and thumb direction vectors into the database used to train the neural network. A 3D environment was created for the introduction of the data describing the gesture into the database. A classification accuracy of 95% was achieved for the hand flexion and extension gesture divided into three levels for each hand. The populated database may also be used to classify other gestures involving hand rotation.

Keywords. Gesture, neural network, leap motion, hand recovery

1. Introduction

As substantiated by the literature, several sensors are used to detect hand gestures. A Flexible Epidermal Tactile Sensor is used to detect five gestures: finger flexion and extension, hand flexion and extension, and the non-state gesture (a gesture that expresses no particular state of the hand) [1]. To classify such gestures, a neural network consisting of 10 input layers was built for each gesture and an arbitrary number of hidden nodes was chosen. A set of 450 data was used to train the neural network, and 50 data entries were used for testing. A gesture classification accuracy of 88% [1] was obtained for the neural network. Image processing is also used to recognize hand gestures. In [2] a neural network is used to detect gestures representing letters, numbers or punctuation marks. Three thousand nine hundred (3,900) images were used to train the neural network. A gesture classification accuracy of 90% was achieved. Numbers and letters of the alphabet expressed by dynamic gestures may also be recognized by using the Microsoft Kinect device. The use of a radial basis function (RBF)-based neural network to classify gestures representing numbers or letters is described in [3]. The experimental results led to an accuracy of 97.25% for the gestures representing the English language alphabet, respectively of 92.63% for the gestures representing the Arabic numerals. The Microsoft Kinect device may be used in hand recovery –hand deviation exercise [4] as well as to monitor the users' correct sitting posture at a computer [5].

¹ Corresponding Author, Stelian NICOLA, University Politehnica Timisoara, P-ta Victoriei no. 2, Timisoara, Romania; E-mail: stelian.nicola@aut.upt.ro.

Judging by the degree of involvement of the limbs and by how recovery is performed, the devices used in recovery may be classified into four categories: passive, active, haptic and coaching devices [6]. Coaching devices are the cutting-edge technology in recovery. They are based on the use of cutting-edge technologies such as virtual reality, augmented reality or mixed reality to train patients on how to perform the recovery exercise. Moreover, they provide feedback to the users on the accuracy of the exercise being performed. The Leap Motion device may also be assigned to this category. It may be used in hand recovery inasmuch as it recognizes hand gestures, but also in monitoring or classifying the evolution of a disease [7] (e.g. classification of Parkinson disease). New recognizable gestures may be implemented for it [8]. The software of this device has four predefined gestures: *Screen_Tap*, *Key_Tap*, *Swipe* and *Circle*. One downside to it is that when using gestures that involve hand rotation, it confuses the left and the right hand. One immediate solution for this issue is the use of 2 Leap Motion devices [9]. The 2 devices are placed on a stand so as to be perpendicular to one another (the first is placed horizontally and the second vertically). The classification of the gestures implemented for the Leap Motion device may be performed with the aid of neural networks [10].

The objective of this paper is to achieve a specific classification for the hand flexion and extension gesture detected by means of a neural network. The Leap Motion device's main issue of recognizing the left hand from the right hand will be eliminated by entering the data corresponding to the hand and thumb rotation direction in the database. The neural network will classify the recovery level 1, 2 or 3 for each hand. The major advantage of the implemented neural network is that it is able to accurately identify the hand being used. Another benefit lies in building the database, which may also be used in training other neural networks for the classification of other types of gestures involving hand rotation.

2. Method

The accuracy of the neural network depends on: the selection of the relevant data describing the flexion and extension gesture and the number thereof, the computation of the number of neurons for the hidden layers of the neural network as well as on the division of the gesture into levels so as to make it usable/functional/useful in recovery. We explain below how the neural network was parameterized in order to achieve the best possible classification accuracy.

2.1. Neural Network

For the clusterization of the hand flexion and extension gesture by levels, we used an open-source machine learning platform (*Tensorflow*), which was parameterized. The neural network consists of 13 input layers and six output layers (Figure 1). A variant on two levels including each 17 neurons was chosen for the hidden layers. The number of neurons for the hidden layers was determined by the following formula:

$$N_h = \frac{N_s}{\alpha(N_i + N_o)} \quad (1)$$

where: N_h – number of hidden neurons;

N_s – number of data in the database (1737);

N_i —number of inputs (13)

N_o —number of outputs (6)

α —an arbitrarily chosen number, taken from the 2-10 range, in our case α is 3 (selected by former experience).

Training and testing the network required the use of the parameterized open-source Tensorflow library. A hand flexion and extension gesture detection accuracy (level classification) of 95% was achieved. A set of 1737 data was used to train the neural network and 786 data entries were used to test it.

Figure 1. The Neural Network

2.2. Database and 3D environment

To devise gestures in the 3D Unity Editor for the Leap Motion device we integrated the Leap Motion version 2.3 Software Development Kit (SDK) into the editor. A 3D game was created in the Unity Editor, based on the hand flexion and extension movement, C# and PHP (Hypertext Preprocessor) scripts were written for functionality, and Python scripts to train the neural network. To have the device work as correctly as possible it was calibrated to a performance of 110 frames per second.

A MySQL database containing 13 types of data describing the hand flexion and extension gesture was created. The data types contained in the database are the following: —left or right hand, hand rotation, hand pitch, and hand yaw, palm position on all the three axes, hand direction and thumb direction. The last six input data, which refer to direction, provide higher precision in hand detection —left or right hand. In terms of data describing the gesture, a choice was made to use the hand and thumb direction because it was noticed that in some cases the Leap Motion software confuses the right hand and the left hand. Thus, such confusion was eliminated and when a hand is detected upon examination of the gesture all the elements of the other hand are deleted by the C# *Destroy(object)* method. To calculate the hand direction or the thumb direction we used the following formula:

$$D_i = \frac{p_i}{\beta} \quad (2)$$

where: D_i —hand/thumb direction and i refers to the x , y or z axis

p_i —hand/thumb position and i —refers to the x , y or z axis

β —angle calculated based on the following formula: $\beta = \sqrt{x^2 + y^2 + z^2}$

To enter the gesture description data a 3D environment (Figure 2) was created with the aid of the Unity Editor, where the users have to control an aeroplane so that it passes through a series of obstacles. The 3D object is controlled by performing left- or right- hand flexion or extension movements. 2 virtual 3D hands from the Leap Motion software package that copy the movement of the real hand were used to allow the users to constantly observe how they move their hand. The Unity Editor and the database were connected via a C# script which refers to another PHP script (Hypertext Preprocessor).

Figure 2. The 3D environment

Certain hand rotation angle ranges were selected, as shown in Table 1 to filter the data based on levels for each hand. The name assigned to each level was given in the following form: *Level_n_H*, where *n* represents level 1, 2 or 3 and *H* represents the left hand *-L* or the right hand *-R*.

Table 1. Ranges for each level of the flexion and extension gesture

Level	Range
Level_1_R	[-180; -60)
Level_2_R	[-60; 60)
Level_3_R	[180; 60]
Level_1_L	[180; 60]
Level_2_L	[60; -60)
Level_3_L	[-60; -180]

A division of the hand flexion and extension gesture into several levels was made because in hand and wrist recovery patients are initially unable to perform a full hand flexion and extension movement. Thus, recovery progress may be observed when moving from one level to the next.

The C# *RiggedHand* script was rewritten to achieve best possible results in the classification of the hand flexion and extension gesture, eliminating, therefore, the possibility for the virtual hands which copy the movement of the real hands to take any virtual position within the 3D space. Such operation was made because as far as the hand rotation gestures are concerned, the data related to distances and positions of the fingers are not important. It may be said that the virtual hands are mobile, but they have a single rotation point.

3. Results and discussion

Table 2 shows the results obtained for each level of each hand. The following metrics were computed: precision, recall, f1-score. It can be noticed that the relation between the training data number is directly proportional to precision. The maximum F1-score is of 0.98 for 675 training data for level 2 of the left hand, while the minimum F1-score is of 0.47 for level 3 of the right hand. Thus, the larger the training data set, the better the F1-score.

Table 2. Precision, recall, f1-score and number of training and test data

Hand Level	precision	recall	f1-score	No. of training data	No. of test data
Level 1 –right	0.94	0.99	0.96	148	152
Level 2 –right	0.99	0.92	0.95	473	146
Level 3 –right	0.31	0.92	0.47	201	12
Level 1 –left	0.83	0.58	0.68	127	52
Level 2 –left	0.99	0.98	0.98	675	368
Level 3 –left	0.92	0.96	0.94	113	56

This paper focused on the creation of a neural network for the classification of the hand flexion and extension gesture recognized by the Leap Motion device. A gesture classification accuracy of 95% was achieved. Emphasis was placed on the correct detection of the hand being used to perform the gesture, eliminating the confusion between the right and the left hand. The database created to train the neural network allows the users to also train other neural networks in order to classify other types of hand rotation gestures (e.g. pronation and supination). The gesture was divided into several levels so as to enable using the gesture in patients' hand and wrist recovery. Our next objective is to use machine learning techniques to detect multiple gestures performed with both hands for the Leap Motion device.

Abstract. Heart Failure is a severe chronic disease of the heart. Telehealth networks implement closed-loop healthcare paradigms for optimal treatment of the patients. For comprehensive documentation of medication treatment, health professionals create free text collaboration notes in addition to structured information. To make this valuable source of information available for adherence analyses, we developed classifiers for automated categorization of notes based on natural language processing, which allows filtering of relevant entries to spare data analysts from tedious manual screening. Furthermore, we identified potential improvements of the queries for structured treatment documentation. For 3,952 notes, the majority of the manually annotated category tags was medication-related. The highest F1-measure of our developed classifiers was 0.90. We conclude that our approach is a valuable tool to support adherence research based on datasets containing free-text entries.

Keywords. Adherence, heart failure, telemedicine, text mining, machine learning.

1. Introduction

Heart Failure (HF) is a severe chronic disease of the heart. For affected patients, an active change of lifestyle regarding nutrition and physical activity as well as individually tailored medication is recommended in the Treatment Guidelines published by the European Society of Cardiology [1]. Telehealth networks like the HF disease management program *HerzMobil Tirol* support patients and all stakeholders involved in their treatment by implementing a closed-loop healthcare paradigm [2]. In a recent publication, Köhler et al. provided evidence that such a telehealth system can improve the outcome of HF treatment [3].

The main aims of HF telehealth solutions typically relate to a) outcomes and b) economics-related targets. These targets can be achieved by early detection of acute HF events. Besides vital sign monitoring, documentation of patients' medication and their

¹ Corresponding Author: Alphons Eggerth, AIT Austrian Institute of Technology GmbH, Reininghausstraße 13, 8020 Graz, Austria, E-Mail: alphons.eggerth@ait.ac.at.

adherence to it are major features to achieve this goal. Medication management is a crucial part of each HF telehealth system. However, medication regimes are often complex, as they are subject to drug-drug-interactions, and should be tailored to vital parameters, individual circumstances, co-morbidities, etc.

Telehealth data may comprise structured data (e.g. vital signs) as well as unstructured, textual entries (e.g. free text notes). For efficient monitoring of drug adherence, data on medication need to be available in a structured fashion. Therefore, *HerzMobil Tirol* is linked to the Austrian drug database (SISIX – Spezialitäten-Informations-System, Apotheker-Verlag) and regimes of drug intake can be specified by the physician. Patients, on the other hand, are requested to document the correct intake of drugs. However, a relevant part of the information regarding medication and adherence is gathered via phone calls by involved nurses, who subsequently create free text notes within the *HerzMobil Tirol* database, mostly, because of difficulties to provide complex information from the patients' side on drug compatibility and adherence as well as from the stakeholders' side on possible changes in the procedure and medication within the structured variables as provided by the telehealth systems. Screening of free-text entries can be used to identify missing input fields, which should be added to the queries for structured treatment documentation. To avoid tedious manual screening of numerous free texts, natural language processing and machine learning can be applied.

In a recent systematic review, Sheikhalishahi et al. give an overview of natural language processing of clinical notes on chronic diseases [4]. The biggest fraction of papers resulting from their literature search was related to diseases of the circulatory system. In the context of HF, various objectives were addressed through natural language processing. Garvin et al. [5] measured the quality of HF inpatient care based on various document types. Watson et al. [6] used electronic health record data to identify psychosocial risk factors related to a higher hospital readmission risk. While those papers deal predominately with in-clinic data, studies have been performed in our group, which focus on the specific requirements in HF treatment via telehealth. Modre-Osprian et al. [7] analysed collaboration notes of stakeholders in their HF treatment network and identified medical and organisational issues. Gruber et al. [8] designed a pipeline to classify free-text notes into task and status categories.

In this study, we analysed the content of all free-text notes found in a given dataset of *HerzMobil Tirol* with respect to medication and adherence information. We tagged the notes with pre-defined categories to potentially reveal missing input fields of the queries for structured treatment documentation. Furthermore, based on the first level of tagging, we developed a classification algorithm, which can be used in subsequent studies to automatically filter numerous free texts to a smaller subset of relevant entries.

2. Methods

2.1. Dataset

De-identified (as described in [8]) data from phases I-IV of the Austrian HF disease management network *HerzMobil Tirol* were used. *HerzMobil Tirol* connects several stakeholders who are involved in the treatment of patients (see Figure 1).

The *HerzMobil Tirol* disease management network started in 2012 with project phase I (feasibility), followed by phase II (proof-of-concept), III (specification of

routine care), IV (preparation of translation to routine care) and V (translation to routine care). Currently, *HerzMobil Tirol* is part of routine care for HF patients in Tyrol.

Within *HerzMobil Tirol*, patients record vital data (blood pressure, heart rate, body weight), subjective wellbeing and medication on a daily basis, using a specific smartphone App. Data are transmitted to a backend service, where authorized health professionals can access the data. Various roles (patient, coordinator, clinician, nurse, general practitioner, relatives, helpdesk) can communicate with each other via collaboration notes. Details concerning *HerzMobil Tirol* can be found in [10].

Our dataset comprised 3,952 notes, which were created during the treatment of 106 patients, who participated in the initial four project phases (2012 – 2016) of *HerzMobil Tirol* (see Table 1).

Figure 1. The *HerzMobil Tirol* heart failure disease management network involves several stakeholders. Clockwise: coordinator, clinician, nurse, general practitioner, relatives, helpdesk. [9]

Table 1. Patient statistics for the initial four project phases of the *HerzMobil Tirol* disease management network. *One patient of project phase II participated also in project phase IV.

Project phase	Monitoring time	Patients	Age (M \pm SD)	Male / female	Notes
-	months	-	years	-	-
I	12	10	72.8 \pm 8.7	2/8	142
II	6	40	75.4 \pm 13.0	15/25	1,746
III	3	15	70.7 \pm 10.0	7/8	494
IV	3	42	66.9 \pm 11.3	8/34	1,570
Total	-	106*	71.1 \pm 12.1	32/74*	3,952

2.2. Note classification via manual annotation and natural language processing

For note annotation, seven categories were defined: *absence of the patient*, *adaptation of the thresholds for vital parameters*, *death*, *medication*, *period of in-clinic stay*, *technical problems* and *therapeutic advice*. Due to the high number of medication-related tags and since the focus of our study was on medication adherence, category *medication* was divided into five sub-categories: *dose adaptation*, *drug added to prescription*, *drug removed from prescription*, *intake-related information* and *reason for prescription change*. For each category, the notes were manually screened for relevant information and tagged correspondingly. The annotation was done with a web application called *Twister*, which has been developed with the Python-based web framework *Django* [11] and is a part of our *Predictive Analytics Toolset for Healthcare (PATH)* [12].

Automated classification was done based on the machine-learning framework *scikit-learn* [13]. A bag-of-words model was used for classification. Stop words were removed and numbers, medication and references to time and units were abstracted. Tokenization was done with *spaCy* (ExplosionAI GmbH, Berlin, Germany) based on a pre-trained German corpus. Classification was done based on linear classifiers using stochastic gradient descent learning. For each category, a binary classifier was trained.

3. Results

Table 2 shows the number of tags for each category as well as the performance measures of the classifiers developed using a total sample size of 2,049 notes (= subset of notes with at least one tag) that were split to training (80%) and test (20%) set for evaluation. While death-related notes were very rare, there were many notes on a period of in-clinic stay. The majority of tags, however, were in the *medication* category. The classifier of the *adaptation of the thresholds for vital parameters* category showed the highest F1-measure, followed by the classifiers of the *period of in-clinic stay* and *medication* categories. For the *death* category, too few samples were available for classifier training.

Table 3 shows the results of the manual sub-categorization of 956 medication-related notes. While *dose adaptations* were the most frequent sub-category, the smallest number of tags was in the *drug removed from prescription* sub-category.

An example of a medication-related note by a general practitioner is: “I adapted the medication regime because of asymptomatic hypotension.”, which was further tagged with the *dose adaptation* and *reason of prescription change* categories.

Table 2. Category tags and performance measures of the trained classifiers.

Category	Tags	Precision	Recall	F1-Measure
Adaptation of the thresholds for vital parameters	146	0.99	0.82	0.90
Period of in-clinic stay	640	0.97	0.77	0.86
Medication	956	0.91	0.80	0.85
Technical problems	354	0.93	0.75	0.83
Absence of the patient	178	0.90	0.58	0.71
Therapeutic advice	180	0.75	0.44	0.55
Death	11	-	-	-

Table 3. Results of the manual sub-categorization of the *medication* category.

Sub-category	Tags
Dose adaptation	287
Intake-related information	253
Reason of prescription change	204
Drug added to prescription	124
Drug removed from prescription	91

4. Discussion

Annotation of the free-text notes revealed that information is mainly provided regarding the *medication*, *period of in-clinic stay* and *technical problems* categories. Therefore, free text notes are a valuable source of additional information for the evaluation of medication adherence in a telehealth HF disease management network. However, manual analysis of every single note is a time-consuming task. Our automated classifiers achieved F1-measures of up to 0.90 with $F1 > 0.80$ for four out of 7 categories. Therefore, our classifiers could be used as an accurate filter of subsets containing only relevant notes, thus sparing researches from tedious screening work.

In the *medication* category, many notes contained intake-related information and revealed the reason for a prescription change. Although it is possible to document addition or removal of a drug or to change the medication dose in a structured way in the system, we found that additional information is often documented in free-text notes,

such as the reason for prescription, or complicated dosage regimes (every second day, dosage depending on patient status, etc.). Hence, a suggestion to further improve the queries for structured treatment documentation would be to add respective input fields.

Collaboration notes were manually tagged with categories by only one of the authors. To obtain a more reliable gold standard for the machine learning tasks, the notes need to be re-tagged by multiple persons independently for subsequent analyses.

In future studies, text mining algorithms should be further developed towards fully-automated information extraction from free texts, like identifying events, dates and values to automatically add them to structured data. Moreover, it needs to be investigated if doing annotation and classification on a sentence level will result in better performance.

In conclusion, our approach for automatic notes categorization is a valuable tool to support adherence research based on datasets containing free text entries, as it allows data scientists to filter a subset of relevant entries.

Patient-Generated Health Data in the Clinic

Nirusha JEEVANANDAN^{a,1} and Christian NØHR^a

^aThe Maersk Mc-Kinney Møller Institute, University of Southern Denmark, Denmark

Abstract. Physician appraisal of Patient-Generated Health Data (PGHD) is unclear. It is not known how willing they are to consider self-registered measurements prior to treatment. In this research, a semi-structured interview was designed and administered to 10 physicians in Denmark. The study found that physicians are willing to work with unsolicited PGHD and integrate it as a part of the treatment if evidence proved the data to be valid and reliable. They request documented evidence for the use of each PGHD device and mobile application.

Keywords. Patient-generated health data, eHealth, Medical wearables

1. Introduction

The health care system is awaiting a revolutionizing paradigm shift, where it becomes more personalized and enable citizens to take more responsibility for their health and well-being. Digitalization in the health sector is increasing all of Europe as personalized medicine, digital innovations, the Internet of things, and artificial intelligence gains momentum [1]. This shift transfers the control of health care from hospitals and physicians into the hands of patients; more specifically, into their homes and mobile devices [2]. It is estimated that the global market for medical wearables will reach \$19.5 billion in 2021 [3]. Patients are becoming more self-reliant in using digital opportunities to maintain their health [4]. Patient-Generated Health Data (PGHD) can be obtained digitally using various devices and mHealth applications. PGHD are health-related data created, recorded, or gathered by or from patients [5]. PGHD is often confused with patient-reported data (PRO-data). In Denmark, PRO-data is described as data about the patient's health, including physical and mental health, symptoms, health-related quality of life, level of functioning, as reported directly by the patient. The collection and reporting of data are requested by the health practitioners. In contrast, PGHD is initiated and driven by individuals, hence a patient-driven data collection modality [6].

It is assumed that PGHD can be instrumental in changing the health care system to focus on health care rather than sick care and to assist patients in being able to prevent many health problems before they become manifest [7]. Despite the growth in the use of PGHD, a literature search indicated a knowledge gap and a lack of evidence-based literature examining physicians' appraisal of PGHD in Denmark. However, the use of PGHD is more common in other countries, mostly in the US, where several health care professionals have worked with PGHD for clinical usage [8]. By accepting and utilizing PGHD, it is possible for physicians to gain greater insight into patients' overall health,

¹ Corresponding Author, E-mail: nirusha.jeevan@gmail.com

from which the physicians can make more informed decisions [9]. Examples of PGHD can be physical activity, sleep, temperature, heart rate, electrocardiogram (ECG), blood pressure, blood glucose, and oxygen saturation. In addition to data captured by sensors, PGHD can be supplemented by patient entered information such as mood [10]. More active patients will result in an increasing number of appointments with self-recorded measurements [7]. The benefits of PGHD can be limited for patients if their physicians do not agree to utilize the collected data, and physicians' appraisal of PGHD is still unclear in many countries. It is not known how willing they will be to consider these measurements prior to treatment, hence the aim of this study is to examine physician's appraisals of unsolicited PGHD and investigate how these data can be applied in the clinic in collaboration with patients.

2. Methods and material

Since the aim of this research is to describe and understand clinicians' subjective appraisal of practical PGHD use, qualitative interviews were chosen as the method. An interview invitation was sent to 17 possible participants from the author's professional network in Denmark. Attention was paid to variation in age and field of specialization. In qualitative studies, it is not possible to determine the minimum sample size, but it was assumed that data saturation could be reached within the 17 respondents. An interview guide reflecting the research questions was developed for the semi-structured interviews. In order to test the set of interview questions, two pilot interviews were performed. Explanations for key terms for PGHD, PRO-data, mHealth, pHealth, and patient empowerment were prepared and used for unanimously describing the terms during the interviews. The need for this description indicates how known these terms were.

10 of the 17 invited agreed to participate, and interviews were conducted in the period from 21-03-2019 to 10-04-2019. The physicians decided the date and place for the interviews. All participants provided consent to the interview and audio recording. The interviews ranged in length from 7 to 36 minutes. The interviews were transcribed verbatim for later analysis.

A deductive analysis approach was applied to derive information on categories from the interview guide, priori concepts, and pre-existing knowledge. The themes and coding categories were: 1) current knowledge of PGHD, 2) Physicians' perspective of PGHD, 3) Future use of PGHD.

To guide the questions and have a specific focus for the interviews, the ECG measurement facility on the Apple Watch, series 4, was demonstrated and used for reference during the interviews. Additionally, pictures of the ECG reading were shown, in the health application and in a PDF file.

3. Results

Generally, the physicians were open-minded about PGHD and the increasing use of mHealth and growing patient empowerment. Some of the perceived benefits mentioned are patients being more liberal, active in maintaining their health, can result in less overload for the physician and also be an assisting tool for the physician. One of the physicians mentions the following: *"I actually think there are some things that might be*

really great if the patients could monitor themselves because then they do not have to show up here to find out things and I also believe in that way it is the relevant patients which come to you, it is not just everyone that comes in, and then you think I am sorry, but I cannot really help you... Whereas you can be some kind of gatekeeper from the start and then the relevant patients come in, now I have this, you can see this is what I have, I want to come in and talk to you."

The results of the analysis of the interviews are presented in Table 1. Some of the concerns expressed were that it could create unnecessary worrying among patients and over-observations, concerns about an increase in the inequality in health and about the

Table 1. The different aspects investigated in the study

Item	Aspect/construct	Responses (n=10)	
1	Not familiar with PGHD	%	70
2	Confused PGHD with PRO	%	30
3	Familiar with the existence of PGHD	%	10
4	Experiences of patients seeking out to them with health-related data generated by themselves without prior being solicited from the physicians	%	40
5	Experienced the increasing use of mHealth and patient empowerment	%	70
6	Worried about patients over-diagnosing themselves and creating unnecessary	%	70
7	Worried about increase/creating an inequality in health	%	40
8	Feels it is a good idea that patients can register own data when symptoms occur	%	20
9	Concerned about data credibility and needs validation of data	%	80
10	Willing to work with PGHD in the future as a part of patient treatment if they find data	%	80

data validity. The majority of the physicians do not trust data validity for the Apple Watch's ECG application and indicated that they would perform their ECG measurements.

The physicians have different opinions about the future use of PGHD. Most of them are willing to use it but have different criteria and necessities. Additionally, physicians reported different ideas for future use where PGHD is included as part of treatment, as well as perspectives on how the data should be integrated as a part of the EHR.

4. Discussion

Overall the physicians were not familiar with the term PGHD. Those who said they were actually confused it with PRO-data, which some of them were familiar with to a certain extent. Although some of the physicians were not familiar with PGHD and the use of it, they already had experienced patients bringing their self-registered data without it being solicited by their physician. Most of the physicians had experienced increasing patient empowerment, except for two of them who work with elderly and mentally ill patients. Most of the physicians were familiar and experienced with the patients' use of mobile health applications and patients looking up their symptoms and diagnosis on Google.

Generally, the physicians are open-minded about PGHD. Some of the benefits and concerns expressed in the interviews replicate results reported in the literature [6, 8], [11–13]. Benefits can be gained not only for the physicians but also for the patients, by

being more active and involved in the decision making for their treatment, thereby becoming more patient-centred. This can likewise help physicians to be diagnostic efficient and effective. The data validity and verification were one of the main concerns mentioned by the majority of the physicians, and it was decisive for their willingness to use PGHD. Concerns about over-diagnosing, patients becoming excessively worried, and making themselves feel more ill than they were, in reality were mentioned repeatedly. Even though the physicians felt that patients became more concerned from generating their data, some of the physicians still had an understanding of why they did so.

Another major concern was an increase of inequality in health among patients. The increasing inequality and deepening of the gap between the “haves” and “have-nots” are also one of the main apprehensions mentioned by Eysenbach as a considerable threat [14]. The concern of the availability of PGHD among low-income and elderly populations and those who often needed it the most was also shared among physicians’ opinions found in the literature [11]. A cardiologist at University of California San Francisco states that the individuals who purchase Apple watches often are those who are already health-conscious and probably quite healthy, whereas those who would have the most benefit from the atrial fibrillation screening tend to be the elderly, who might be less tech-savvy and less concerned about their health [15]. In addition to worried patients, this situation can also induce a greater workload for the physicians.

Many of the physicians emphasize the importance of not only looking at measurements but also at the patients’ symptoms. They would consider forwarding the patient to a cardiac specialist if the symptoms were significant and the ECG still showed a sinus rhythm. Generally, in this research, it was discovered that most of the physicians did not fully trust the ECG application on Apple Watch. Most of them were open to looking at the ECG reading brought by the patients but would then use their own verified device, e.g. a Holter. However, according to Cardiologist John P. Higgins, the updated capabilities of the Apple Watch Series 4 can broaden the monitoring capabilities of existing technologies. He states that *it is less invasive than Holter monitor, has great battery life and can be with the person 24/7* [16].

American physicians share the concerns of their Danish colleagues about the lack of evidence to justify the Apple Watch ECG against the risk of false positives. The latter would cause healthy/wealthy people to take up the time resources of both physicians and hospitals since there is no evidence that the benefits outweigh the harm. At the same time, another American physician states that for people with heart conditions or symptoms, the Apple Watch could serve as a good tool for detecting when something is wrong and when a visit at the physician is necessary [15]. This research shows that the physicians are willing to use PGHD as a part of treatment, as long as their individual criteria and needs are met. Some of the needs reported in the literature [13], such as making time to review PGHD, uncertainty of data quality and the need to distinguish between data measured by patients and by health care professionals.

Most physicians agreed with integrating PGHD into the EHR, as was already done according to [17]. Many of their future ideas for the use of PGHD is likewise based on importing the data into the EHR. However, it was important for physicians to be able to distinguish between the data collected by themselves and by the patients.

Despite the different opinions about PGHD and the benefits that can be gained by using it, and likewise the increased workload and burden for the physicians, it is clear that the first priority among the physicians is the safety of the patients. They do not wish to place all responsibility on the patients. They want to make sure that the devices and mobile applications can be trusted while avoiding unnecessary patients worry.

5. Conclusion

This qualitative study showed that Danish physicians sampled have an overall positive appraisal of PGHD for clinical usage. Despite the many clinical benefits to be gained, the physicians prioritize data from validated, and reliability checked sources before taking it into consideration for clinical decisions. The physicians appreciate increasing patient empowerment and are willing to use PGHD as a part of the treatment for those who have the resources and desire to do so. Additionally, the physicians welcome importing PGHD into the EHR, as long as they are clearly marked. The physicians request more studies and documented evidence for the use of each PGHD device and mobile application; therefore, further research is needed to achieve a general appraisal.

Register-Based Research of Adverse Events Revealing Incomplete Records Threatening Patient Safety

Ulla-Mari KINNUNEN^{a,1}, Eija KIVEKÄS^a, Sari PALOJOKI^b, Kaija SARANTO^a

^a *University of Eastern Finland, Department of Health and Social Management, Finland*

^b *Ministry of Social Affairs and Health, Finland*

Abstract. Inadequate, missing or incorrect patient information is usually related to poor documentation. It has several negative effects on patient care processes, and, thus to quality of care, care continuity, and patient safety. It is one of the causes of patient claims. The aim of this study was to analyze patient safety reports and to find out which documentation hazards are damaging to patient safety. Data consisted of the patient incident reports (n=82 353) from seven health and social care areas from 2007–2016 in Finland. A descriptive analysis was conducted to explore the type of service provider and incidents reporting risks in patient data management and documentation. Adverse events due to patient data management and documentation were unusual; however, 18 cases were documented where patients suffered serious harm. Nearly half of the reports resulted from inadequate, missing or incorrect information. Uniform structures, documentation, and service processes need to be developed.

Keywords: Documentation, safety management, patient harm.

1. Introduction

The transition from paper-based patient documentation systems to electronic systems has been widespread during the past years both internationally [1] and in Finland [2]. Some existing evidence shows that computerized patient data management systems [3–4] and electronic documentation systems [5] affect positively patient safety and quality of care. In addition, structuring electronic health records can have an impact, e.g., on decreasing medication errors, increasing documentation quality, and on care process efficiency, care guidelines conformation and decreasing of prescription errors [6]. However, in some cases, despite classifications [7] or electronic systems [8] in use, the quality of documentation is weak [3,4]. Thus, poor or missing documentation is among the most common causes for patient claims. Poor documentation hinders the visibility and evidence of health care professionals' competencies, compliance of standardized care procedure and clinical guidelines, quality of care, the assessment of the health care provider, and the defence against claims [9].

One of the aims of the Finnish Patient and Client Safety Strategy 2017–2021 published by the Ministry of Social Affairs and Health [10] is that by 2021, all electronic health service processes and procedures will be safe, and patients and clients protected from harmful incidents. This also includes patient data management and documentation where all the essential processes in information flow and documentation must be

¹ Ulla-Mari Kinnunen, Virranniementie 3, 78310 Varkaus, Finland; E-mail: ulla-mari.kinnunen@uef.fi. +358403553953

actualized using the same formats and structures in every health and social care organization, and in information exchange between the organizations. In addition, professionals in health and social care will have access to information systems and patient or client information that support their work and their processes [11]. A large number of incidents related to information management consist of documentation errors. Inadequate, missing or incorrect information, e.g. wrong name or birthday, might stand for some specific information loss. This might have a very important role, e.g., in the continuity of care and more, in patient safety [12].

Common data structures and structured patient data benefit broadly and in various ways, both the patient, professionals, and organizations [6, 13]. The Finnish patient safety incident reporting system, HaiPro, [14] is widely used in national health and social care. The online reporting system allows reporting of incidents for professionals, but also patients and their families. The aim of this study is to analyze incident reports and especially concentrate on finding out which documentation hazards are most damaging to patient safety.

2. Methods

Data consisted of the incident reports (n=82 353) from seven health and social care areas from the years 2007–2016: three hospital districts, health and social care of two large cities, and two social and health care districts. Reports were retrieved from the Finnish Society for Patient Safety database, which collects reports from about 200 health and social care facilities. Reports include both structured and free-text descriptions of safety events.

A descriptive analysis was conducted to explore the type of service provider (primary, health and social care) and incidents reporting risks in category *Information flow and information management related*. HaiPro [14] system has 13 incident categories (Table 1). In addition, the reporter describes the incident by narrative text clarifying the type, context, and circumstances of the incident. The consequences for patients or service providers are also assessed. Reporting incidents is confidential, voluntary, and anonymous, highlighting learning from mistakes and blame-free actions. HaiPro system implementation began in hospitals in 2007, and the social service began implementing the HaiPro system just recently. Reports of inadequate, missing or incorrect information were by inpatient wards and outpatient departments.

Table 1. Categories of HaiPro system

Categories		
1	Medication or iv fluid care, blood transfusion, or contrast agent related	8 Devices or their use related
2	Information flow and information management related	9 Hygiene related/protection against infections
3	Diagnoses related	10 Injury
4	Surgical procedures related	11 Paramedical services related
5	Invasive procedures related	12 Violence
6	Other care related	13 Deviation in radiotherapy
7	Laboratory, imaging-related	

The analyzed adverse events consisted of reports of primary healthcare, special healthcare (hospitals) and social care (i.e., elderly service). Approval of the University

of Eastern Finland Committee on Research Ethics was required. SPSS 23 software was utilized for analyzing the structured data (Armonk, NY, IBM).

3. Results

Adverse events during *Information flow and information management* (n=12 294) comprised 41.2 % (n=5070) of incident reports concerning *Patient data management and documentation* (Table 2). Of those, more detailed description of the incident reports of *Patient data management and documentation* included 40.8 % (n=2066) were the reports of inadequate, missing or incorrect information. Analyses showed that the relative proportion of adverse events was similar in primary healthcare as well as secondary and tertiary healthcare. In both sections, half of the adverse events were reports from inpatient wards. Of all data obtained, most of the reports (63,2 %) came from registered nurses and physicians 4,2 percentage.

Table 2. Information flow and documentation related adverse events

Information flow and information management related adverse events (n = 12 294)	n	%
Patient data management and documentation	5070	41,2
Care coordination	4686	38,1
Verbal communication	2538	20,7
Patient data management and documentation related adverse events (n = 5 070)	n	%
Inadequate, missing or incorrect patient information	2066	40,8
Error in personal data or contact information	576	11,4
Patient information not retrieved or printed from patient records	413	8,1
Wrong or outdated information in patient records	376	7,4
Missing referral or inadequate, missing or incorrect information in referral	329	6,5
Information input or retrieval of patient records hindered	306	6
Referral of test result documentation for wrong patient	215	4,2
Patient information documented in wrong place	201	4
Other or unknown	588	11,6

When reporting, the nurse or physician picks the incident category and the applicable harm that he or she thinks has occurred to the patient. In most cases (59,2 %, n = 1948), as a consequence, no harm was done to patients due to adverse events of *Patient data management and documentation*. Patients suffered from moderate harm in 178 (5,4 %) cases and serious harm in 18 (0,5 %) cases. Five of those serious cases were related to inadequate, missing or incorrect information. Not knowing the degree of harm were 10.8 % of the cases (n=166) which related to inadequate, missing or incorrect information.

4. Discussion

Uniform, accurate, and standardized data structures and documentation are a prerequisite to safe and good-quality care [6]. Inadequate, missing or incorrect information can be

very important information. It may be essential for patient care which has an explicit connection to patient safety [3-5,12]. There are a lot of differences in the structures of patient care documentation [13]. Over one-third of the incident reports of *Information flow and information, management* were related to *Patient data management and documentation*. Of those reports, nearly half were of inadequate, missing or incorrect information. This information deficiency can be, e.g. missing information about patient's medicine or allergy, which cannot be seen in the electronic documentation system. It can also be inadequate documentation of medicine administration, a missing patient identifier in a laboratory test, or wrong electrocardiogram for a physician to interpret.

Adverse events related to patient data management and documentation included a total of 18 cases where the patient suffered serious harm. Most of these incidents were because of inadequate, missing or incorrect information. Lack of and deficiencies in documentation likely refers to poor-quality care and missing standardized care processes [7]. Adverse events related to *Patient data management and documentation* can refer to inoperative work and operational practices, which means that professionals need to be trained simultaneously when implementing a new system [10-11].

Documentation deficiencies can also be an outcome of inoperative and unclear documentation systems [7] or lack of rules and requirements for documentation [8]. These need to be taken into account in the early stages of the electronic documentation system's acquisition and when defining the common documentation guidelines for both organizational and national levels [6, 11]. Advances, such as improved data quality and patient's legal protection, decreased misinterpretations, better possibilities for data re-use and data retrieval, and possibilities for decision support connection to patient records and its use have been presented. This also applies to the use of standardized health and social care languages [6, 13].

The purpose of HaiPro system is highlighting learning from mistakes [9, 14]. Accurate documentation is evidenced to affect patient safety, and the main criteria for high-quality healthcare are considered to be well-trained staff and treatment that works [3-5]. Incidents of *Patient data management and documentation* occurred both in primary and special healthcare. Our data illustrated that the handling process requires confirmation.

5. Limitations

Data for this study represent seven health and social care districts. However, our data included safety incidents reported by the largest hospital district in Finland, which accounts for approximately one-third of the population. Due to the voluntary nature of the HaiPro incident reporting system, not all incidents are reported. In the future, more emphasis should be put on how the systems can be made more comprehensive and more effective.

6. Conclusion

Good quality and accurate documentation **are** known to affect patient safety positively. Organizations need to plan and implement standardized documentation platforms and care processes. Additionally, we need more accurate information on adverse events and understanding of the problem for improving health and social care processes. Even

though the amount of serious harm to the patient because of inadequate, missing or incorrect information was not big in this data, this example shows the value of incident reporting systems. Patient safety must never be harmed because of poor documentation.

Teletriage Pilot Study (Strategy for Unscheduled Teleconsultations): Results, Patient Acceptance and Satisfaction

Andrés Santiago FRID^{a1}, María Florencia Grande RATTI^b, Ana PEDRETTI^b, Marina VALINOTI^b, Bernardo MARTÍNEZ^b, Janine SOMMER^a, Daniel LUNA^a, Fernando PLAZZOTTA^a

^a*Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*

^b*Internal Medicine Research Unit, Hospital Italiano de Buenos Aires, Argentina*

Abstract. Non-urgent consultations to an Emergency Department (ED) contribute to overcrowding. Telecommunications represent a potential strategy to reduce some face-to-face consultations. Objectives: To describe characteristics of patients who used the Teletriage Program during the pilot study, to explore safety and to report user acceptance and satisfaction. Methods: Cross-sectional study, including all adult patients affiliated to our health insurance attended to via this telemedicine service between January 18th and May 31st, 2019 (during pilot-study). Patients were followed-up for seven days to assess re-consultation to ED or unscheduled hospitalization. Results: 276 effective consultations occurred, corresponding to 241 patients, with a mean of age of 50 years, 68% (189) were women. Chief complaints were related to clinical issues (70%) and remaining (30%) were administrative problems. Only four patients were suggested a referral or face-to-face assessment. Rate of re-consultation to the ED was 18% (51) at seven days of follow-up, and the rate of unscheduled hospitalization was <1% (2), both with good clinical evolution. Patient satisfaction was 72.73%, and regarding acceptability, 66.12% stated that without this channel they would have attended to a face-to-face consultation and 64.02% that they would do so if their needs remained unmet. Conclusions: Implementing this new communication channel could be a useful and safe strategy to reduce unnecessary non-urgent consultations to the ED.

Keywords. eHealth, mHealth, teletriage, telehealth, telemedicine

1. Introduction

Non-urgent consultations to the Emergency Department (ED) contribute to a phenomenon known as overcrowding [1]. Evidence suggests that telemedicine plays an important role in evaluating patients that would otherwise attend to the ED. On the one hand, support by remote pre-hospital electrocardiogram for patients with suspected acute cardiovascular disease proved to avoid unnecessary hospitalizations and to confirm correct diagnoses, by-passing delays in the ED and therefore lowering mortality and costs [2–4]. Furthermore, the use of a telemedicine consultation program significantly decreased neuro-emergent stroke patient transfers from rural hospitals to

¹ Corresponding author: Santiago Andrés Frid. E-mail: santiago.frid@hospitalitaliano.org.ar

urban settings, while increasing stroke specialist reading of patient imaging studies within 3 hours of the onset of stroke symptoms [5]. This experiences, as well as previous evidence on the use of telecommunications as a strategy to reduce non-urgent consultations to the ED [6], have reported reducing costs through a safe intervention [7], with elevated acceptance by users [8].

Our institution implemented a virtual program for low complexity respiratory teleconsultations during the epidemiological outbreak of Influenza in 2018, which proved to be a safe and effective strategy [9]. In that project, we perceived unmet clinical and administrative needs, which prompted us to implement a broader program for mild symptoms and non-urgent clinical consultations for adult patients.

The objective of this article is to describe the characteristics of patients who used this service during the pilot study, as well as to explore patient acceptance and satisfaction with the use of this tool.

2. Methods

Observational, descriptive, cross-sectional study at Hospital Italiano de Buenos Aires, a high-complexity hospital located in Buenos Aires, Argentina, that has its health insurance called Plan de Salud (PS) with over 150,000 affiliates. Our average daily rate of consultations to the ED is 500, 50% of which are attended to at a low complexity walk-in area with an admission rate below 1%.

Teletriage program was implemented and made available during the pilot period, on business days between 4 P.M., and 8 P.M. Consultations were initiated by patients through their Personal Health Records (PHR) via desktop or mobile devices, and attended to and registered by physicians in the EHR, with a structured form designed ad hoc. Variables in this form were used as secondary databases for the retrospective data collection.

We included all adult patients affiliated to PS who performed a teleconsultation between January 18th and May 31st, 2019. We excluded all teleconsultations with failure to communicate (initiated but not answered), non-effective consultations (failure with video, audio or chat, or with interruptions to the communication that could not be by-passed through an effective phone-call) or those with no complete structured form in the HER. Patients were followed-up for seven days from the date of teleconsultation to assess re-consultations to the ED and hospitalization.

Additionally, we evaluated waiting times (measured as the difference between the moment that the patient checks in and the moment in which the physician initiates the communication), patients' acceptance of the tool (through two mandatory questions to users before teleconsultation) and patients' satisfaction (measured through Telehealth Usability Questionnaire -TUQ- adapted from English [10]).

Mandatory questions with multiple-choice options were: (1) If this communication channel did not exist, what would you do? (A- Attend to a face-to-face consultation: walk-in clinic, ED; B- I would not carry out any consultation; C- Solicit an appointment with a physician; D- Use another Telemedicine system) and (2) If you could not solve your chief complaint through this teleconsultation system, what would you do to solve it? (A- Attend to a walk-in-clinic or ED, B- I would not carry out any consultations, C- Solicit an appointment with a physician).

Quantitative variables are presented according to distribution as means and standard deviation (SD), or median and interquartile range (IQR) or 25-75 percentiles.

Categorical variables are presented as absolute frequency and relative frequency (percentage). Rates are presented as prevalence, with its 95% confidence interval.

This research project was approved by the institutional review board. Confidentiality was guaranteed. There were no potential risks for patients.

3. Results

There were 476 virtual consultations registered. After applying exclusion criteria, we had a total of 276 effective consultations with a complete structured form, pertaining to 241 patients (see **Figure 1**).

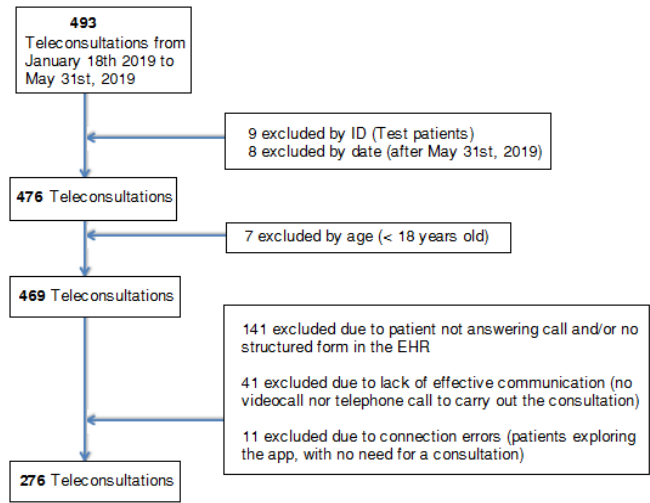

Figure 1– Flow chart of included patients

Service was offered for 90 days during the study period. Patients had a mean age of 50.46 years (SD 19.45), including patients from 18 to 97 years old, and 68.47% (189) were women. Data of care process was registered in EHR. Majority of chief complaints were clinical issues (detailed in **Table 1**) and solved through this channel. Administrative cases were related to drugs prescriptions or information, appointments, vaccines prescription, test results and medical information.

Table 1. Consultations and patient attention process

Chief complaint	n: 276
Administrative	29.34% (81)
Clinical	70.66% (194)
Respiratory	18.11% (50)
Infectious	17.75% (49)
Pain	13.76% (38)
Gastrointestinal	13.40% (37)
Gynaecological	3.98% (11)

Cardiological	2.89% (8)
Mental Health	0.77% (2)
Referral (ED, walk-in centre, doctor home visit)	1.44% (4)

The physician suggested a referral for a face-to-face assessment for only four patients (1.44%). At the seventh day of follow-up, the rate of re-consultation to ED was 18.47% (51), and the rate of unscheduled hospitalization was 0.72% (2), due to an asthmatic crisis and dehydration respectively. One patient had been referred to the ED while the other was already on her way to ED (during teleconsultation was carried out). Both had good clinical evolution.

In terms of waiting times, we found a median of 4 minutes (RIQ 9) and a mean of 7 minutes (SD 7.16).

As to patients' acceptance of this communication channel, 667 patients answered the mandatory questions (some never effectively checked in for a teleconsultation, and others experienced technical difficulties). 66.12% stated that without this channel, they would have attended to a face-to-face consultation and 64.02% that they would do so if their needs were not met with Telemedicine.

Regarding satisfaction assessment, 110 patients answered the TUQ (response rate of 23.45%). The percentage of patients that agreed 7/7 with the statements of the questionnaire were as follows: 'I am satisfied with the use of the system' (72.73%), 'I would use it again' (76.36%), 'Telemedicine is an acceptable way of receiving provision of healthcare' (73.64%), 'Teleconsultations are equivalent to face-to-face consultations' (28.18%), 'I am comfortable communicating with the physician via the Telemedicine system' (74.54%), 'I could see the physician as if I saw him in person' (52.73%), 'I could hear the physician when using the system' (57.27%) and 'I would recommend the Telemedicine system of HIBA to other people' (74.55%).

4. Discussion

This pilot study shows that implementation of an unscheduled teleconsultation program was a useful and safe strategy to meet patients' needs, representing an innovative and feasible experience for our institution, in compliance with recent suggestions by our Health Ministry for the development of Telemedicine in Argentina.

Additionally, based on emerging legal and moral consensus on hospitals' obligations towards its surrounding communities, Emergency Departments should not be treated as mere sources of admissions [11]. Therefore, management strategies such as this one are needed in order to improve the functioning of a collapsed system.

In consistence with our previous work, many chief complaints were administrative [9], which could be due to delays in patient attention in the outpatient setting. Our pilot also showed a high rate of satisfaction and acceptability. The lower percentages in patient satisfaction regarding how users saw and heard physicians were in line with the technical difficulties some patients experienced. This is mainly due to poor home Internet connections, which are highly prevalent in our country.

Lessons learned throughout this project will fuel improvements needed before implementing it at a larger scale. In consistency with evidence in the literature, we detected most usability issues in the initial phase of implementation of the telemedicine

system [12]. These issues prompted us to carry out a redesign of the tool and the process at the end of the pilot, with results that will be reported in the near future.

There are certain limitations to our study that need to be addressed. Real re-consultation rates can be underestimated since we did not take into account consultations to peripheral walk-in clinics that are part of our institution because we were unable to collect such information retrospectively. The analysis was also affected by effective teleconsultations not registered in the structured form in the EHR, due to the elevated number of physicians assigned to this project (higher possibility of errors in the process). The TUQ response rate was 23.45%, which could suggest a potential information or response bias, a denominator of self-selection or volunteer effect that has been reported in the literature [13], and it was adapted from English but not validated [14].

In accordance with the literature [15], we believe that part of our success was due to the existence of a local framework and the involvement of an interdisciplinary team, the activity of institutional communication channels, and the support provided by the Health Informatics Department, which allowed us to prioritize the caregiving process, maintaining efficacy of the workflow and improving providers' trust on the project.

Abstract. Chronic kidney disease (CKD) is a Public Health problem affecting a considerable number of patients worldwide. CKD treatment is complex and requires patients' education. Based on this we have created technological tools, including an application for smartphones and a profile on Instagram (Renal Health) aiming to educate patients to self-monitor and cope with their disease, to increase adherence to treatment. In this study, we have analyzed the spontaneous feedbacks patients, and other people have posted on the Renal Health Instagram (comments) to investigate which information was needed the most by which types of patients. During the first 15 months since the release of this profile, there were 3380 followers, a total of 449 posts, with 36,079 "likes". Most of the followers were patients and parents, they gave spontaneous testimonials of their experiences with having kidney disease, and were thankful for the information provided and for the response we gave to their questions. From the analysis of the comments, we found that information on nutrition, physical activities and kidney transplant were the most discussed and valued. Our results also showed that the main use of this medium for dialysis and transplant patients was to share their experience. The Renal Health Instagram was considered a good digital platform of trusted information for both patients and the general population and also a space for sharing experiences in the context of kidney disease epidemics.

Keywords. Kidney disease, patient empowerment, internet, Instagram, education

1. Introduction

Since 1980 debates regarding health promotion are advancing in Brazil, with focus on the multi causality of diseases and the right to health, culminating in the creation of the Brazilian Unified Health System (SUS), which is now one of the largest Public Health Systems in the world, with free universal coverage [1]. Since the creation of the SUS,

¹ Corresponding Author: Prof. Geraldo Bezerra da Silva Junior, Programa de Pós-Graduação em Saúde Coletiva, Universidade de Fortaleza, Av. Washington Soares, 1321. CEP 60811-905. Fortaleza, Ceara, Brazil; E-mail: geraldobezerajr@unifor.br.

health education is valued, and patients are considered as crucial in the process of healthcare and the management of their care, to have an active role for achieving a good health condition [2].

This protagonism of patients in healthcare is crucial in the context of chronic disease, as in the case of chronic kidney disease (CKD). CKD is currently a worrisome Public Health problem, which affects approximately 11-13% of the general population. This reality is not different than in Brazil, where these rates have grown, having a 27% increase of patients on hemodialysis from 2012 to 2017, and in 2018 there were more than 130,000 people receiving dialysis [3]. The main causes of CKD are hypertension and diabetes, which are controllable, require patients' education and collaboration to change their habits. Therefore, educational measures are crucial, and technology can help.

Recent data shows that more than 70% of internet users claim to have searched for health information in the past year [4]. In Brazil, recent data from the Ministry of Planning, Development and Management showed that 74.9% of households have internet access, and 97% of the population has a smartphone [5]. Although there are many sources of information on the internet, many are neither trusted nor valid. Therefore, there is a need to create educational material, with a multidisciplinary team, which can be frequently updated [2, 6]. In this way, patients and people who connect with our social networks and other technological tools that we create can have easy access to qualified professionals, who cannot be so easily accessed in regions where access to health is limited, such as in poor and developing countries. In addition, one size does not fit all. Therefore, the aim of our study was two-fold: first, we aimed to analyze the effects of a recently created social network for patients with kidney disease (the Renal Health Instagram) through their spontaneous comments, using the internet and smartphones as a way of getting information for health education.

2. Methods

The Renal Health project started in 2015, aiming to develop technological tools for patients, and the public in general, to get information about kidney disease in Fortaleza, Brazil, including an application to help CKD patients in their treatment [6]. Although the fifth largest city in Brazil, Fortaleza, still faces several problems, including poverty, lack of sanitation, unemployment, and difficulties with access to health care, we have the possibility to offer technological tools to help people cope with chronic diseases, and they have easy access to the internet. All this makes health education essential to achieve better results in terms of decreasing the burden of chronic diseases. In the most recent official document about the mortality causes in Brazil, CKD appeared as the 10th most common cause of death in this region [5]. We created an Instagram profile and a YouTube channel to educate people, using not only text but also movies. We posted information about nutrition, medication use, physical exercises, and several other aspects of kidney diseases, prevention and treatment, on a weekly basis. The profile can be accessed through this link: https://www.instagram.com/renal_health/. We analyzed the spontaneous feedback people who follow the Renal Health Instagram profile have given from 1st June 2018 to 8th September 2019. Aside from analyzing all the feedback given in this period, including a quantification of the "likes", we specifically analyzed the posts that were most commented on, and what type of information was required the most by which type of kidney disease patients. An analysis of the testimonials and

acknowledgements was also done, in order to identify which groups of patients and people were most “reached” by the information provided by the Renal Health Profile so that in the future posts we could offer more tailored information based on these patients’ needs. We have analyzed all the posts of the profile (“Renal Health” Instagram), as well as each comment and feedback, and made a classification based on the subject. It consisted of a content analysis. Subsequently, we have made a characterization of the socio-demographical profile of the followers.

3. Results

Since the first publication in the Renal Health Instagram profile on June 1st, 2018, we have gathered a total of 3380 followers. In total there were 449 posts: 14 (3%) about medication, 63 (14%) about nutrition, 9 (2%) about excesses, 123 (17,39%) about kidney disease and comorbidities, 70 (15,59%) about treatment stimuli, 55 (12,2%) about kidney transplants and organ donations, and 35,78 % others. Virtually all posts received “likes” and comments. A total of 36,079 likes have been observed, and the post that has received the highest amount of “likes” (n=837) was one regarding organs’ donation.

Of a total of 1381 comments, these comments were performed by 469 profiles, of these are 80 (17%) men, 350 (74.6%) women and 39 (8.3%) profiles without gender, noting the prevalence of women among the comments made. One hundred eighty-five (185) comments were posted regarding congratulations and acknowledgements on the profile (Figure 1). People were thankful for the fact that our profile is interactive, and all questions are answered. We have identified 95 patients with kidney disease, mainly CKD. Of these, 73/95 (63.1%) spontaneously reported their illnesses in their comments, being on 60.2% dialysis, 21.9% transplanted patients, 6.8% glomerulonephritis, 5.4% kidney stones and 5.4% renal cysts. In total, 95 patients had posted spontaneous testimonials about their diseases and experiences with having CKD, and the difficulties they had faced. Also, 28 acquaintances of patients with kidney diseases had posted comments on our publications, most regarding questions to help them cope with the care of their children.

Table 1. Types of themes posted in the Renal Health Instagram, June – September 2019.

Posts category	Number of posts
Medication	14
Nutrition	63
Excesses	9
Kidney disease and comorbidities	123
Treatment stimuli	70
Kidney transplants and organ donations	55
Others	115
	449

Figure 1. Testimonials of patients following the Renal Health Instagram, showing the impact on their habits and lifestyle. On the right side, a testimonial showing a patient’s lifestyle change, and on the left, a tattoo with our project’s logo in a patient’s arm in a sign of gratitude and comprehension of the aims of the project.

The most commented posts were: 32 posts with comments on nutrition, followed by kidney transplants (with 29 comments), totalling 61 comments. From 90 comments that were posted in the groups of 45 patients on dialysis, there were 14 comments covering the questions on this topic, 68 comments of personal experiences on the subject, and finally eight comments on the importance of this information. In the group of 12 patients having kidney transplantation, 11 comments demonstrated their happiness after the transplant and their experiences, followed by one comment covering a question about their happiness after the transplant and their experiences. We have also identified other health professionals interacting with the profile, declaring that it was useful to help them to give advice to patients. And finally, this platform had crossed the borders, since we have also identified comments by people from other parts of the world, such as other South American countries, the Middle East and Europe.

Table 2. Types of comments from 45 dialysis patients posted in the Renal Health Instagram, June – September 2019.

Types of comments from dialysis patients	Number of posts
Questions on the topic	14
Personal experiences on the subject	68
About importance of this information	8

4. Discussion

The Renal Health Instagram showed to be a valuable digital platform for patients with kidney disease and surpassed the initial objective of the researchers, which was to provide information to patients and caregivers. Our results showed that methods of dialysis and treatment of chronic kidney disease were the most important information for the patients with dialysis and transplantation, followed by nutrition. Our results also showed that the main use of this media for dialysis and transplant patients was to share their experience.

Currently, Medicine and healthcare, in general, cannot be practised without technology and connecting with patients. According to Meskó (2017), there are very interesting new terms in Medicine, for example, the “e-patient”, which can be defined as the patient who is “empowered, engaged, equipped, enabled, equal, or expert”, and “Participatory Medicine”, which is “a model of cooperative health care that seeks to achieve active involvement by patients, professionals, caregivers, and others across the continuum of care... to increase patient satisfaction and improve the cost of care” [7].

The use of social networks, such as the Renal Health Instagram, by patients and the general population, as a way of getting trusted information for health education is benefic, and a real way of connecting patients and the healthcare team in a trusted relationship. Using these platforms, a broader audience can be reached, cross the borders, as the internet can be easily accessed from any part of the world. As technological tools may empower patients with information and abilities to cope with

chronic diseases, medical recommendations might be better followed and therapeutic goals achieved. It is expected that treatment's adherence increases, and therefore complications might decrease, and outcomes might improve. Clinical trials are needed to test this hypothesis.

There are few studies analyzing the impact of the use of Instagram on patients' health education. In a study regarding the use of this social media in the area of Orthopedics, posts on Instagram were predominantly from patients, and fewer were made from doctors [8]. These posts had in the majority of cases positive comments [8]. Another study evaluated the experience of patients using social networks regarding Twitter and Instagram to discuss their experience about a specific surgery (Gamma Knife stereotactic radiosurgery), and the authors evidenced that the main use of these media was to share patients' experience [9], which is accordance with our findings for transplant and dialysis patients. To the best of our knowledge, this is the first study to extract information need for specific types of CKD patients using comments of the provided general information for CKD patients in an internet social network. Future studies are needed to analyze bigger dataset to identify the specific information needs of CKD patients.

5. Acknowledgements

We are very grateful to the International Society of Nephrology (ISN) and the Edson Queiroz Foundation/University of Fortaleza for the financial support given to the Renal Health project. We also thank the Brazilian Research Council (CNPq) and the Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico (FUNCAP) for research grants provided for GBSJ and JGRO during the development of this study.

Use of Social Media Apps by Nurses for Professional Purposes in Catalonia: Cross-Sectional Study

Antonio TORREJON^a, Octavi RODRIGUEZ-BLANCO^a and Miguel A. MAYER^{b,1}

^a *Nursing Association of Barcelona (COIB), Barcelona, Spain*

^b *Research Programme on Biomedical Informatics, Hospital del Mar Medical Research Institute and Universitat Pompeu Fabra, Barcelona, Spain*

Abstract. Over the last few years, the use of social media mobile applications or apps (SMAs) has increased exponentially. The potential advantages of using these technologies by health professionals in clinical settings have been discussed many times. Considering that the nursing profession is the largest segment of the healthcare workforce in the majority of countries in the world, the impact of using these apps by these professionals is very relevant. The objectives of this study were, firstly, to determine if nurses were using SMAs professionally and the most frequent SMAs used and secondly, to find out if, among nurses, there is a need for training in the use of these mobile applications for professional purposes. The study is a descriptive cross-sectional study based on an Internet survey of 1,293 nurses in Catalonia (Spain). The average age of the respondents who had these apps installed on their mobile phones or tablets, was 43.12 (SD \pm 11.32) years old. WhatsApp was the most frequent SMAs used by nurses for professional purposes, and 79.2 % of nurses mentioned they used it several times a day. WhatsApp was the preferred SMAs for communicating with colleagues (31.2% of nurses) followed by Facebook (18.4%) and Twitter (11.3%). In contrast, the use of the SMAs was much less frequent as a means of communication with patients (7.2% in the case of WhatsApp). Nurses expressed their need for specific training in the use of these apps for professional purposes, indicating the interest and potential impact of the introduction of these technologies in clinical environments. The use of SMAs is quite common among nurses at the moment of the survey, and WhatsApp was the most popular one to support their professional activity. Based on the results of the survey, the Nursing Association of Barcelona (COIB) will consider the design of specific training activities in the use of SMAs in clinical settings.

Keywords. Social media, nurse role, survey, mobile health

1. Introduction

Over the last few years, the use of social media platforms and mobile health applications (apps) has increased exponentially. The potential advantages of using these tools by professionals in clinical environments have been discussed in several forums [1-3]. Currently, there are a lot of social media apps (SMAs), and Facebook,

¹ Corresponding Author: Miguel Angel Mayer, migueangel.mayer@upf.edu.

YouTube, Twitter, WhatsApp, LinkedIn, Pinterest, Tumblr or Instagram are among the most frequent ones[4-6], which are available to assist health professionals with many different tasks. Some of these tasks allow us to work in collaboration, to communicate with patients and other professionals, to perform patient management and monitoring, health education, training and research [7,8]. Nevertheless, it is not clear enough how to use these technologies in clinical settings considering the different aspects mostly related to ethical and legal aspects such as privacy of personal data and security [9].

Considering that the nursing profession is the largest segment of the healthcare workforce in the majority of countries in the world, including Spain [10, 11], the impact of the use of mobile applications by nurses, is highly relevant in the future of modern healthcare.

The objectives of this study were, firstly, to determine if nurses were using SMAs professionally and the most frequent SMAs used, and secondly, to find out if, among nurses, there is a need for training in the use of these mobile applications for professional purposes. The survey included questions about the use of SMAs and also health apps for professional purposes. In this paper, we present the results of the study related to the use of SMAs.

2. Methods

The study is a descriptive cross-sectional study based on an Internet survey of 1,293 nurses in Spain. LimeSurvey [12], an open-source platform, was used to gather the information of the survey online. In March 2018, an e-mail, including a link to the website with the survey, was automatically sent to the 26,907 registered nurses who had a contact e-mail in the Nursing Council of Barcelona (COIB) of Catalonia [13]. COIB is the second-largest Nursing Council in Spain with 34,327 registered nurses. The e-mail also included information about the purpose of the survey and that the information gathered would be analysed anonymously. After the first e-mail, two more e-mails were automatically sent as reminders within the following 30 days.

The survey consisted of 34 questions organised in three parts: (1) questions related to sociodemographic and professional information such as age, gender, workplace and professional activity or speciality, (2) questions about the use of social media and health apps for professional purposes and finally, (3) questions asking for the training needs for using SMAs for professional purposes. This paper is focused on describing the characteristics of the respondents and the use of SMAs for professional purposes. The description of the use of health apps for professional purposes was published in another journal [14]. Descriptive statistics were applied for all the items in the survey using the R programming language version 3.4.2 importing a .csv file with all the data. The governing board approved the study of the Nursing Association of Barcelona.

3. Results

The percentage of respondents to the survey who used SMAs for professional purposes installed on their smartphones or tablets was 46.4% (600/1,293). The remaining 693 respondents said that they did not use apps for professional purposes and were not included in the analysis. The average age of the respondents was 43.12 (SD \pm 11.32) years old, and there were no significant differences between the age of men and women

(t=-1.5078, $P = .1336$). The distribution of age was: 16% baby boomers (> 56 years old), 58% generation X (between 35-56 years old) and 26% millennials (< 35 years old). Concerning the professional area, most nurses worked in hospitals (48%) and primary care (24%). The remaining respondents worked in social healthcare (7%), management (5%), pre-hospital care (4%) and teaching/research (3%). Regarding the specialisation, the most frequent groups were general nursing (53%), medical-surgical (14%), paediatrics (8%) and family and community (7%).

Regarding the frequency of use of SMAs for professional purposes, WhatsApp was the most frequent SMAs used for professional purposes. 79.2 % of nurses reported using WhatsApp several times a day, followed by Facebook (28.7% several times a day), without significant differences comparing hospital and primary care use ($p=0.220$). Instagram, Twitter and Skype were not so frequently used for professional purposes. Overall, nurses preferred smartphones (91.2%) instead of tablets (8.8%) for managing SMAs professionally. Figure 1 shows the frequency of use of the seven most common SMAs as a means of communication, according to the respondents of the survey. WhatsApp was used preferably as a means of communication with colleagues (31.2% of nurses) as well as Facebook (18.4%) and Twitter (11.3%). Nevertheless, the use of these SMAs was much less frequent as a means of communication with patients (e.g. 7.2% in the case of WhatsApp). Most of them (81.8%) considered that it was necessary to receive specific training in the use of SMAs in professional environments, without significant differences among age groups and gender ($\chi^2=3.40$; $P=.347$).

Figure 1. Use of social media apps by nurses for professional purposes

Most devices were less than two years old (77.0%), and 42.7% of the devices were less than one year old. As for the operating system, 51.1% had Android, and 45.7% had iOS. Table 1 shows the proportion of nurses that were using different SMAs as a means of communication with patients and professionals. WhatsApp and Facebook are the most frequently used SMAs as a means of communication with other professionals.

Table 1. The proportion of nurses that were using different social media apps as a means of communication with patients and professionals.

Social Media Apps	With patients (%)	With professionals (%)
Facebook	5.0	18.4
Twitter	2.2	11.3
LinkedIn	1.5	9.4
Instagram	1.2	4.5

WhatsApp	7.5	31.2
Skype	2.2	6.84
Youtube	1.8	3.0

4. Discussion

Over the last few years, the evolution of smartphones and other devices, as well as the applications developed, have evolved at an unprecedented rate. Our study shows that the use of SMAs is common among nurses (46.4%), being WhatsApp and Facebook the most frequently used apps to communicate with other professionals, as is the case of other health professionals such as medical doctors [6,15]. In contrast, the use of these apps is not frequent to communicate with patients. It could be of interest to know the content of these communications and the reasons why nurses use SMAs instead of other means of communication, considering that it is necessary to take into account different ethical and legal aspects when using these apps for professional purposes. Most likely, the ease of use and immediacy are the main reasons to use these SMAs.

The majority of nurses expressed their interest in receiving training in the use of mobile applications, indicating the potential impact of the introduction of these applications in clinical settings. It is essential to promote the training of nurses, and health professionals in general, who must be trained in the use of mobile applications, wearables or telemedicine applications. Currently, there is a need to analyse the specific advantages and drawbacks as well as consider all the aspects related to the use of these technologies among clinicians and it is necessary to analyse the ethical, legal, technical and security aspects to introduce SMAs in healthcare services [16-18]. In addition, the interoperability and the integration of SMAs in electronic health records should be evaluated very carefully to guarantee the quality, correctness and the compliance of all the legal and ethical requirements of each healthcare system. More experience is needed to determine the actual use and clinical usefulness of these technologies [19,20].

This study has some limitations, on the one hand, the number of participants in the survey was low compared with the number of nurses who potentially received the survey, and for this reason, the results could overestimate or underestimate the real use and interest of nurses in social media tools introducing a selection bias. On the other hand, the survey did not include all the types of SMAs available on the Internet that may be used by nurses. As far as we know, there are no other studies of the same characteristics in Spain or other countries that are focused only on nurses [1,6,15].

5. Conclusions

The use of SMAs is quite common among nurses at the moment of the survey. The most popular SMAs used by nurses to support their professional activity is WhatsApp, which was mostly used as a means of communication with other colleagues. Nevertheless, the use of SMAs is not as frequent as a means of communication with patients in clinical settings. Nurses expressed their need for specific training in the use and applications of SMAs for professional purposes, indicating the potential impact of the introduction of these technologies in clinical environments. Based on the results of the survey, the COIB will consider the design of specific training activities for nurses in the use of SMAs for professional purposes in clinical environments.

Acknowledgements

Special thanks to all the nurses of the Nursing Association of Barcelona (COIB) who participated in this study.

Abstract. In traditional West African medicine, most practitioners are illiterate for official languages. 1127 local languages exist in this region. The transmission of knowledge in this traditional medicine is notoriously oral. In order to enable practitioners to communicate and preserve this knowledge, we are building SysMEDTRAD, a traditional medicine management system, based on a formal ontology of traditional medicine called ontoMEDTRAD. To overcome the language and illiteracy barriers, we propose to combine realistic photographs of plants with formal iconic descriptions of plants and recipes. This paper presents the formal and automatized representation of traditional African medicine recipes.

Keywords. Ontology, Traditional medicine, ontoMEDTRAD, West Africa, Iconic composition, Non-verbal communication.

1. Introduction

Traditional medicine (TM), despite the progress of modern medicine (MM), still exists. Without seeking to replace or to copy the MM, and even less to be obliterated by it, the TM practiced in Africa and especially in its western part, persists and knows a renewed interest at the dawn of the 21st century. This resurgence is partly justified by the fact that the populations health care needs are insufficiently covered by the MM. In addition, health care costs in MM are often expensive and prohibitive for the disadvantaged social groups [1]. Without any discrimination, almost all social classes, for their health and medical needs, even if they use MM, continue to refer to TM. About 80% of the population commonly uses TM [15]. In West Africa, and particularly in rural areas, every inhabitant knows and uses the therapeutic properties of a number of plants. We are therefore talking about popular medicine. In this part of Africa, we count 15 countries and 1127 local languages [13]. Thus, TMP (Traditional medicine practitioners) face a huge language barrier. Moreover, the majority of them do not know how to read nor to write the official languages. They speak them with difficulty or not at all. Knowledge of TM is widely transmitted orally, when it is not kept secret. Academic and research institutions related TM are almost non-existent in these countries. Most of these TMP are illiterate (the illiteracy rate varies from 65% to 80% [8]) and belong to a wide linguistic and cultural diversity. Consequently, a visual

¹ Corresponding Author, e-mail: kgerappoh@gmail.com

approach can be more appropriated for supporting the collaboration between TMP and also the preservation of TM knowledge.

SysMEDTRAD [2] aims at addressing this problem. It includes ontoMEDTRAD, an ontology of West African TM associated with a visual approach. ontoMEDTRAD is divided in two modules: a terminological module ontoCONCEPT-Term, and an iconic ontoICONE. In a previous work [2], we proposed a formal method for representing medicinal plants with icons. Here, we extend this representation with realistic photographs and we propose iconic recipes of plant-based medicines, automatically generated from the ontology. We focused on malaria [8], one of the most morbid and deadly diseases in Africa.

2. Background

Concerning TM, Ayimdji A. [5] made some tools in Cameroon, but without a visual approach. An ontology for African TM [4] from G. Atemezang, has its object focused on the validation of knowledge managed by a system of agents. It does not address the fact that the TMP are mostly not literate. In Côte d'Ivoire, VetoMed [6] of K. Brou explores some visual aspects, but does not contain an ontology.

Regarding MM, LAMY J.B. *et al.* proposed an iconic language named VCM (Visualization of Concepts in Medicine) for representing symptoms, disorders, treatments and follow-up surveillances [12]. VCM is equipped with formal semantics defined in an ontology [11]. VCM aims at facilitating and speeding up the access to medical data and knowledge, rather than crossing the language barrier.

3. Materials and methods

We carried out field visits to TMP accompanied by translators, in Côte d'Ivoire and Senegal. We collected TM documents from NPTMP, the National Program of TM Promotion (Côte d'Ivoire) and some NGOs such as PROMETRA (Sénégal). Given the highly implicit and hidden nature of TM, we have conducted sensitization activities with 50 Ivorian TMP to increase their openness and their commitment to the project. The Abidjan-based NPTMP manager played a facilitating role in these activities alongside the TMP. We also visited 59 Senegalese TMP, mainly in the Saint-Louis region. From published works [1, 10, 3, 9, 8, 16], we extracted 31 traditional medicines for treating malaria with 28 recipes made of 22 distinct medicinal plants. We extracted realistic photographs of these plants from Wikipedia.

We followed an incremental and progressive general approach. First, we considered three use cases for our system: identifying the plants for a given recipe, preparing the medicine, and administrating it to the patient. We structured the pieces of information describing the medicines and the recipes in a formal ontology of TM. This ontology was manually modelled using the Protégé editor. We also collected various concepts from existing top ontologies (*e.g.* open biological ontologies (OBO), general formal ontology (GFO) and descriptive ontology in linguistics and cognitive engineering (DOLCE)) and domain ontologies (*e.g.* plant ontology (PO) [14]).

Second, for describing and identifying plants, we combined two approaches: realistic photographs showing the leaves and the fruits, and icons showing the main botanic criteria permitting the identification of the plant. Candidate criteria were

extracted from botanic sources [3], and then selected according to their discriminant capacity, as determined by the Weka Ranker and JRIP modules, as described in our previous works [2]. The resulting criteria were integrated into the ontology.

Third, plant icons are obtained by combining various iconems (*i.e.* small pictograms or colors), each corresponding to a specific value for a given criterion. Three strategies were used for visual representation, inspired by Peirce: analogy *i.e.* visual similarity, index *i.e.* semantic association and symbol *i.e.* arbitrary conventions [7]. Iconic recipes are obtained by the juxtaposition of one or several ingredients. Each ingredient is a part of a plant, and is represented graphically by the photographs and the icons of the plants, and a small icon representing the part of the plant used (*e.g.* leaves or roots). Iconic recipes are then enriched with icons representing the preparation and administration modes.

Finally, pictograms were drawn using the Inkscape vectorial drawing software. The icons and iconic recipes are generated as Scalable Vector Graphic (SVG) image files, automatically from the knowledge in the ontology, using Python scripts and ontology-oriented programming with the OwlReady module [11]. These scripts combine the pictograms and colorize them as needed excepted leaf for which green color is retained.

4. Results

Figure 1: UML model of TM recipes and medicines.

The resulting ontology, previously described in [2], uses the *ALCHOIQ* Description Logic. Figure 1 shows the UML model of the plant-based medicine and recipe in ontoMEDTRAD. A medicine is characterized by a recipe and one or more administration modes (*e.g.* oral route, nasal route with fumigation, topic application during bath, ...). The recipe includes one or several plant-based ingredients and a preparation mode (*e.g.* decoction, infusion,...). Each ingredient is described by a plant and a part of a plant, using functional object properties. This ensures the uniqueness of ingredients.

The criteria retained for describing plant icons are given in Figure 2, with an example of icon for the plant *azadirachta indica* A. Juss.

Figure 3 gives an example of iconic recipe and its decomposition in icons. This recipe has two ingredients : leaves of *Azadirachta indica* A. Juss. and leaves of *Senna occidentalis* L. It is prepared as a decoction and the resulting medicine can be administered orally or in a bath. We included a total of 28 herbal recipes and 31 herbal antimalarial medicines in the current ontoMEDTRAD ontology.

5. Discussion and conclusion

In this paper, we proposed a formal method for the visual and iconic presentation of plant-based recipes in traditional West African medicine. This approach relies on a formal ontology of TM, namely ontoMEDTRAD.

Many ontologies exist for MM. However, it stands important differences in the way the patient is managed. In TM, diseases are detected by signs and symptoms that are clues and not necessarily by clinical examinations of MM. While remedies of TM are used in their almost natural state, MM often uses a synthetic product chain bound to a chemical industry. Unlike MM practioners, the TMP is at the same time a "physician", a "pharmacist" and a "nurse. Hospitalization and surgery are very rare in TM. Consequently, we did not reuse existing MM ontologies.

A few ontologies were proposed for TM [5, 4]. However, they are embryonic and they lack of medical validation. They also miss the information required for the visual presentation of plants as icons, e.g. they do not include the color of flowers and fruits. Therefore, we preferred to design our own ontology.

In addition to plant icons, we have included realistic photographs of the plants.

Figure 3: Example of iconic recipe (on the left) and examples of pictograms (on the right) (Numbers between parentheses indicate the number of distinct possible values for each criterion).

Both icons and photographs are visual presentation and description of the plant. They are highly complementary : the photographs allow an immediate recognition of the typical plant individuals, while the icons permit recognizing plant individuals that are significantly different from the photographs, *e.g.* due to the variability of the same plant species according to the various ecosystems, thanks to the botanic criteria that characterize the species. Pictograms were drawn by ourselves, however, they could be improved by a professional graphic designer without modifying the semantics and semiotics of our work. Both icons and photographs allow overcoming the linguistic barriers for TMP. A short training is probably needed before TMP fully understand our iconic language.

This work is part of a larger project aimed at the modernization and the valorization of West African TM. The main perspectives of the present work are : (1) the extension of the iconic and photographic presentation to other concepts such as symptoms, disorders, or mineral and animal medicinal resources; (2) the validation of the proposed visual presentation with TMP; (3) the integration of the visual presentation in a semantic wiki, allowing TMP to collaborate and to write and read medicinal recipes online.

^bBern University of Applied Sciences, Bern, Switzerland

Abstract. *Background and objective:* The number of publications on the use of chatbots for health is recently increasing, however to our knowledge, there are no publications summarizing what is known about using chatbots for public health yet. The objective of this work is to provide an overview of the existing scientific literature on the use of chatbots for public health, for which purpose have chatbots been used, and whether health-related outcomes have been reported. *Methods:* We carried out a literature review on this topic across 5 databases: Pubmed, EMBASE, PsychINFO, SCOPUS, and IEEE Xplore. Identified papers were classified according to their underlying technology, application area, and study design. *Results:* A total of 15 relevant papers were identified: eight of these papers were developmental studies that tested the feasibility or usability of a chatbot, and seven were interventional studies. All the interventional studies reported positive health-related outcomes associated with the chatbot use. *Discussion:* The first studies testing chatbots for public health seem very promising; however, there are various aspects that should be improved, including the chatbots' designs, studies' methods, and analysis and reporting of results. More high-quality studies and improved reporting of chatbots' use are needed.

Keywords. Chatbot, public health, mHealth, public health informatics

1. Introduction

Public health is defined as the branch of medicine concerned with the prevention and control of disease and disability, and the promotion of physical and mental health of the population on the international, national, state, or municipal level. One of the main concerns of public health is the growing burden of chronic diseases, which highlights the urgent need to create and make available interventions that can reach large populations at a low cost [1].

Fully automated self-help interventions based on chatbots could serve as highly cost-effective health promotion interventions for large groups of people. Chatbots are computer software programs based on statistical learning, statistical analysis and educational theories aiming at simulating a human conversation by text or voice message, that are easy to use and do not require familiarity with a specific user interface. Although the number of publications on the use of chatbots for public health

¹ Corresponding Author: Elia Gabarron. Norwegian Centre for E-health Research; P.O. Box 35 N-9038 Tromsø (Norway); E-mail: elia.gabarron@ehealthresearch.no.

is increasing, this is still a small and emerging field [2-4], and to our knowledge, there are no publications summarizing what is known about using chatbots for public health yet.

The objective of this work is to provide an overview of the existing literature on the use of chatbots for public health, what kind of underlying technologies have been used, for which purpose have chatbots been used, and which health-related outcomes have been reported.

2. Methods

In order to get an overview of how chatbots have been used for public health purposes, we carried out a literature review in July 2019. We searched for research articles involving the use or testing of a chatbot for public health purposes, reporting results that were published from 2015 until July 2019. The search strategy covered 5 databases (Pubmed, EMBASE, PsycINFO, SCOPUS, and IEEE Xplore) and comprised the following keywords: "chatbot" or "conversational agent" or "relational agent" or "dialogue system" or "Siri" or "Alexa" or "Cortana" or "Google Home" or "Google Assistant" in combination with "public health"; "health promotion"; or "health education". Relevant identified papers were then classified according to technology, application area, and study design.

3. Results

A total of 140 publications were identified in the initial literature review. After removing duplicates, and excluding publications for being out of scope, or not reporting any clinical outcome, we ended up with 15 publications.

Among the 15 included studies, 14 were based on an own developed chatbot, and only one study used a commercially available chatbot [5]. Four studies focused on voice-only chatbots [6-9], and 11 studies used a text-based or hybrid chatbot [5, 8-17]. Voice-only chatbots for public health purposes were tested only in feasibility or usability studies and were developed to provide counselling. Only four of the chatbots were connected or integrated with different social media or website, i.e. LINE, Wikipedia, WhatsApp, and WeChat [11, 12, 17, 18], and four more referred to chatbots connected to sensors or other Apps [10, 14, 15, 19].

Regarding the study design, eight of the papers showed results related to the development of a chatbot, including usability or feasibility studies [6-12, 14]. The chatbots from these eight developmental studies focused on motivating users to control or reduce their weight [11, 14], and to provide different kind of health information, such as HPV vaccination [6], medication [7], breastfeeding [10], diabetes [12], atrial fibrillation [8], and spinal cord injury [9]. Participants involved in these eight papers described the chatbots as easy to use [6, 8], engaging [11], and were positive towards using chatbots or were satisfied with them [7-10, 12, 14].

Seven of the included papers were interventional studies where health-related outcomes linked to chatbots' use were reported [5, 13, 15-19]. All of these interventional studies used a text-based or hybrid chatbot, and the bot was used to motivate and to provide counselling on healthy lifestyles and wellness [18, 19], to improve mental health [5, 16], to reduce reproductive health preconceptions [13], to

encourage loss of weight [15], and to motivate smoking cessation [17]. Table 1 summarizes the reported health-related outcomes in these interventional studies.

Table 1. Health-related outcomes reported by the 7 interventional studies

Reference	Health domain	Reported results (intervention duration)
Gardiner [19]	Healthy lifestyle/wellness	Chatbot group: significantly decreased alcohol consumption, and increased daily fruit consumption (1 month)
Souza [18]	Healthy lifestyle/wellness	100% of participants loved the experience of receiving incentives from the chatbot (1 week)
Ly [16]	Mental health	Chatbot group: participants who adhered to the intervention showed significant positive effects on psychological wellbeing and perceived stress (2 weeks)
Inkster [5]	Mental health	Significantly improvement in symptoms of major depression and a higher proportion of positive experiences among high chatbot users (3 months)
Jack [13]	Reproductive health	Chatbot use was significantly associated with a higher proportion of preconception risks being resolved (6 months)
L'Allemand [15]	Weight control/obesity	70% of participants had >4 interactions per day with the chatbot, and 37% of the daily challenges were completed successfully (4 months)
Wang [17]	Smoking cessation	Chatbot groups: much higher quit rates (2 months)

4. Discussion

Fifteen relevant papers on the use of chatbots for public health were identified in a literature review. Eight of them were developmental studies that only tested the feasibility or usability of a chatbot, while seven were interventional studies. All the interventional studies used a text-based or hybrid chatbot and reported benefits linked to its use, including significant increase in fruit consumption and wellbeing, improvement in depression symptoms, higher proportion of preconception risks solved, and higher smoking quit rates; as well as significant decrease in alcohol consumption, and positive experiences with interacting with the chatbot.

Nowadays, the role of chatbots in the public health system is still limited. Nonetheless, chatbots could provide auxiliary care through providing counselling and encouraging self-management of illness [3], adherence to treatment [20] or administrative services such as scheduling appointments [21], among others. With the continuous advancement in technology and behavioural sciences research, the competency and trustworthiness of chatbots are expected to be increased and promote its use in more complex and significant tasks in the health organizations [3]. First studies testing chatbots for public health seem very promising; however, there are various aspects that should be improved, including the chatbot design, study methods, and analysis and reporting of results.

Regarding the chatbot design, although there is evidence showing higher effectiveness of digital interventions when they are linked, integrated or delivered

through social media [22-24], only a few studies connected or integrated the chatbot to social media or other apps. The connection of chatbots to social media and integration of information from various apps and sensors would make chatbots more tailored to each individual, substantially enhancing the usefulness and motivation for the users to relate to chatbots – thus better possibilities to improve health parameters.

On the study methods, very few studies carried out an intervention, and many of these papers were of very short duration (down to 1 week), and consequently, increasing the likeliness that the positive effects were caused by the "Hawthorn effect" [25] – not the chatbot. More randomized trials should be done on this topic, and future research should increase the duration of the interventions to prove its sustained effect over time.

Better analysis and reporting of results are also needed. It is important to take into account that two of the papers that reported benefits, both of them testing the chatbot in the field of mental health, reported that the positive effect was only present in participants who adhered to the intervention, or that had higher use of it [5, 16]. Adherence to digital interventions is correlated with the characteristics of the innovation, and also with participants' interest towards it [26]. Therefore, and in order to move this field forward, it is relevant that researchers report, analyze and discuss usage metrics and determinants of attrition linked to the chatbots use in health interventions [26]. Security issues related to the chatbot are also a relevant issue that was unconsidered or unreported in the included papers, even though security is crucial in the health domain, and especially relevant for systems that are collecting or processing data from a user. Another security risk that needs further consideration is the possibility of chatbots to motivate the user to do actions that could be dangerous for the individual (e.g. obese person with type 1 diabetes who wants to lose weight, not eating due to encouragement from a chatbot – ending up in hypoglycemia – hospitalized or even dying). Who assumes responsibilities for these risks and the possible dangers, and therefore must be addressed by researchers?

Our literature review has covered five databases; however, we might have missed additional relevant publications on the use of chatbots for public health. Future reviews should expand the scope of the search and incorporate research projects that are being carried out currently, in order to have a better overview of the potential different uses and benefits that chatbots could have for public health in the near future.

Although there are promising results, there is not enough evidence supporting the use of chatbots for public health yet. More high-quality studies and improved reporting of chatbots' use are needed.

A Stroll Along the Erroneous ePrescription Interactions Within the Belgian Pharmacy

Sven VAN LAERE^{a,1}, Ronald BUYL^a and Marc NYSSSEN^a

^aDepartment of Public Health (GEWE), Vrije Universiteit Brussel, Belgium

Abstract. After the national introduction of the ePrescription in Belgium to the broader public in 2014, community pharmacists are still not satisfied completely. Reasons are (1) low acceptance of the implementation due to slow systems, (2) high reported downtimes, and (3) alert fatigue due to technical and incomprehensible error messages. Therefore, we investigated which technical errors occur in the flow of handling an ePrescription and how these errors can be avoided. A cross-sectional design was used to capture interactions of all national community pharmacists connected to the national eHealth platform on a randomly chosen working day. Per interaction, the number of errors made was observed. In total, 567,883 interactions were registered and analyzed, of which the getPrescription interaction, to download the ePrescription from the national server, was most prevalent ($n = 196,433$; 37.21%). A difference of 14,961 interaction calls was observed without reaching a final state (delivered or undelivered). Reasons for these differences are repetitive calls for obtaining the ePrescription or by trying to obtain the prescription again when this should no longer be possible (e.g., when an ePrescription is already delivered or archived). When looking at the markAsDelivered, markAsUndelivered or markAsArchived interactions, most of the technical handling errors are due to attempts that generate not allowed state transitions. Most of these incorrect state transitions could have been avoided by maintaining the state diagram in the pharmacist's system to enforce legal transitions and by training the community pharmacists to handle ePrescriptions appropriately.

Keywords. Electronic prescribing, community pharmacy services, eHealth

1. Introduction

The Belgian electronic prescription (ePrescription) system consists of the typical 3Ps model between prescriber, patient and pharmacist [1]. The electronic prescriptions are securely transferred from the prescriber to the pharmacist, selected by the patient. Typically, from the back-office of the pharmacist, this flow is extended to a price-fixing service that is responsible for the billing to the patients' health care insurances in the name of the pharmacies, since a third-party payment system applies in the Belgian healthcare system [2].

In Belgium, the ePrescription works in a decentralized way where the ePrescription is stored on a central database server, in an encrypted manner. The prescribers send their prescriptions in XML-coded format to this national server, whereafter the patient may visit his pharmacist of choice to get his prescription delivered. Currently, the patient still

¹ Sven Van Laere, Department of Public Health, Vrije Universiteit Brussel, Laarbeeklaan 103, 1090 Brussels, BELGIUM. Tel: +3224774424; Fax: +324774000; Email: Sven.Van.Laere@vub.be

receives a paper proof of the electronic version, which possibly will vanish after the dematerialization phase where the government wants to avoid unnecessary paper use. Currently, the paper-based proof of electronic prescription serves as an access token and feedback mechanism for both the prescriber and the patient so that they can verify what was prescribed. On top of this paper proof, a unique Recip-e ID (RID) barcode is printed, identifying the electronic prescription in the Recip-e database so that the pharmacist can easily retrieve the ePrescription from the national database, by scanning the barcode.

However, even after five years of successful deployment, enabling ambulatory care providers prescribing and delivering of ePrescriptions, care providers are still unsatisfied with this system in place. Closed fora for pharmacists in Belgium[4] report about (1) low acceptance of the implementation due to slow systems, (2) high reported downtimes of the eHealth services, and (3) a raised alert fatigue due to error messages that are written in a technical language that are uneasy to understand for the pharmacist.

The Belgian ePrescription follows the state diagram represented in Figure 1. It corresponds to the “normal workflow” related to handling medical prescriptions in a community pharmacy. Initially, when the prescriber submits an ePrescription, this prescription is in the state *undelivered*. When the community pharmacist retrieves the ePrescription of the national server via the *getPrescription* interaction, the state changes into *inProcess*. When the pharmacist does not have the product in stock, the pharmacist should trigger a *markAsUndelivered* interaction so that the patient can get his drug delivery at another pharmacist. The status is then returned to *undelivered*. When the state of the ePrescription is *inProcess*, the community pharmacist might decide to revoke the prescription, when he, for example, thinks the prescribed medication can be harmful or irrelevant for the patient, by the *revokePrescription* interaction that sets the state of the prescription at *revoked*. The ePrescription will now no longer be available for other pharmacists. When the pharmacist decides to fill the prescription, he can trigger a *markAsDelivered* interaction, putting the state at *delivered*. Eventually, the ePrescription will be sent from the pharmacy that made the delivery to a price-fixing service, thereby informing Recip-e using the *markAsArchived* or *markAsArchivedBis* interaction, putting the prescription in the end state *archived*. All of these interactions use a RID argument to indicate on what ePrescription they want to perform their action.

The low perceived acceptance, high perceived downtimes and growing alert fatigue raised the question of investigating the reason for this. Therefore, we investigated which technical errors in the flow of handling ePrescriptions happen by searching errors in the audit trail of the interactions performed on ePrescriptions and how these errors can be avoided.

2. Methods

In this study, we used a cross-sectional study design where all ePrescriptions’ interactions were taken under the loop to observe the audit trail of interactions taking place at the pharmacy. We, therefore, chose to observe a random day in the delivery process, i.e. Friday, September 6th, 2019. Experiences of the Recip-e organization show that we have to multiply this number by about 25 times to obtain an estimate of the monthly reported number of interactions that take place. The reason for not multiplying

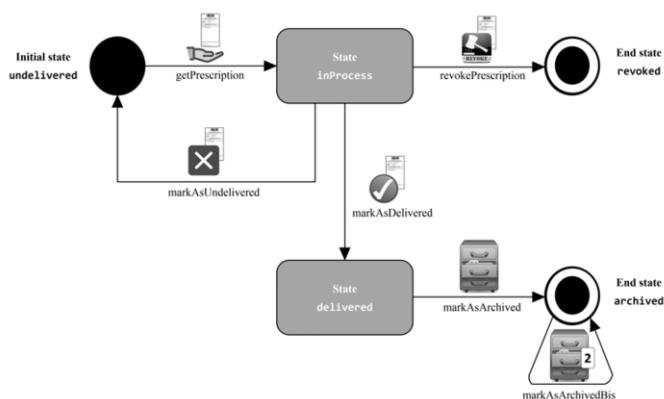

Figure 1. State diagram of Belgian ePrescription when received by the community pharmacist

this amount by 30 is that during weekends, Belgian citizens require fewer medications to be prescribed or filled than during weekdays.

The types of errors that occurred were identified and quantified by reporting the number and percentage of occurrences within the collected sample. The technical errors occurring were categorized as errors to be avoided by a good software implementation or as errors to be avoided by the community pharmacist user (by memorizing the state diagram presented in Figure 1 and actions taken).

3. Results

In the collection of the sample of September 6th 2019, a total number of 527,880 digital interactions of the community pharmacist were observed (see Table 1). Of this total number of interactions, 196,433 (37.21%) were *getPrescription* interactions, where the pharmacist tried to retrieve an ePrescription. When observing the number of interactions bringing the ePrescription from the initial undelivered state to the revoked state or the delivered state, we observed respectively 11,632 *markAsUndelivered* (2.21%), 39 *revokePrescription* ($< 0.01\%$) and 169,801 *markAsDelivered* interactions (32.17%). The sum of these interactions adds up to 181,472 interactions or 92.38% of the total number of *getPrescription* interactions. So, we found a difference of 14,961 ePrescription calls that requested the download of an ePrescription without being handled in a final form. A possible explanation lies in a total of 2,533 repetitive *getPrescription* calls where the ePrescription was already in a state no longer allowing to be fetched again (states archived, delivered, inProcess). The other differences ($n = 12,408$) are to be explained by the further manual processing of the prescription like they used to do when a paper-based prescription was used.

3.1. Incorrect *getPrescription* interactions

When observing the reason for these 2,533 repetitive *getPrescription* interactions, we observed that the highest number of repetitive calls occur when the ePrescription is already archived ($n = 1,547$; 60.60%). This type of error can be explained by the fact that a community pharmacist archives his prescriptions digitally towards a price-fixing

Table 1. Interactions performed on one day, and the number of errors made per type

Interaction	Total nr of interactions	Total nr of pharmacies	Nr of errors	Percentage of errors (%)
getPrescription	196,433	4,688	2,553	1.30
markAsDelivered	169,801	4,667	1,419	0.84
markAsUndelivered	11,632	3,645	534	4.59
markAsArchived	147,901	4,211	1,302	0.88
markAsArchivedBis	2,074	890	-	-
revokePrescription	39	26	-	-
TOTAL	567,883	4,859	5,808	1.02

service and tries to retrieve the digital content a second time. However, since the content has already been archived, its retrieval is no longer possible. Also, copies of the paper proof of prescription that were already delivered and archived at a different pharmacist will result in this incorrect state transition. This type of transition was observed in a total of 367 community pharmacists, of which 279 community pharmacists took care of the archiving of ePrescriptions themselves. It is expected that the user could avoid errors emanating from the user’s pharmacy as the user’s system should keep track of the handling of electronic prescriptions processed at this pharmacy.

3.2. *Incorrect markAsDelivered, markAsUndelivered or markAsArchived interactions*

The remainder of the incorrect calls deal with the *markAsDelivered* (n = 1,419), *markAsUndelivered* (n = 534) and *markAsArchived* (n = 1,302) interactions. Comparing this number of incorrect calls to the total number of interactions made of that type, we respectively obtained 0.84%, 4.59% and 0.88% of incorrect calls (see Table 1).

The main reason for all of these incorrect interactions is again the triggering of an incorrect action coupled to a not allowed state transition: (1) 1,005 of the 1,419 incorrect *markAsDelivered* interactions (70.82%); (2) 518 of the 534 incorrect *markAsUndelivered* interactions (97.00%); and (3) 1,302 of the 1,302 incorrect *markAsArchived* interactions (100.00%). All these incorrect state transition attempts were rejected but could have been avoided by the user when the state diagram, presented in Figure 1, would be memorized by the pharmacist and would be correctly enforced by the pharmacy system.

Other incorrect calls that were made could have been avoided by generating a correct call, i.e., at least giving a RID code as argument when a *markAsDelivered* call was generated (414 out of 1,419 calls; 29.18%) or using a correct RID code when a *markAsUndelivered* interaction was called (16 out of 534 calls; 3.00%). A good software implementation could additionally help verify these checks.

4. Discussion and conclusion

In this research, we showed that on an average working Friday, the Belgian community pharmacists jointly make 527,880 interaction calls with the national database in order to retrieve, (un)deliver, or revoke the ePrescription. This total amount does not include other calls being made by the prescriber to generate and store the ePrescription in a secure way to the server via the national eHealth platform. Five years after national deployment was initiated, still lots of problems related to slow responses, high downtimes and alert fatigue due to technical and incomprehensible error messages are perceived by the community pharmacist. This cross-sectional research tried to find reasons, by looking at the digital

interactions and errors made during interaction that takes place at a community pharmacy with the ePrescriptions on a randomly chosen working day.

About 1.10% of the interactions of pharmacists resulted in attempting to make a technically invalid interaction with the national database. Community pharmacists then typically get a quite technical message of their software stating something about the current status of an ePrescription. However, most of the community pharmacists do not understand these error messages, that in the end trigger their alert fatigue. An example of such a message is “Retrieval of ePrescription failed - [ERR100028] ePrescription BEP1PDT1F5SP is archived”. Here an incorrect state transition was requested.

Most of these error messages are easy to avoid, keeping the allowed state transitions in mind. This status follow-up should be tracked as well by the pharmacy software, but often this is not the case. However, when a patient presents the Belgian proof of ePrescription to a pharmacist, who does not know of earlier interactions in a different community pharmacy, these errors may seem odd and not appropriate. All too often, the pharmacist still tries to execute this prescription, possibly in its paper-based form [2].

Clearer alerts could help in the prevention of this type of errors. Also, clear instructions for the community pharmacist of what state transitions are allowed could help to this. In Belgium, future pharmacists are trained to work with digitalized systems by doing internships in different pharmacies. However, when this state diagram is not present in the mindset of tutoring community pharmacists, the tutor during the internship will not be able to guide the intern correctly.

An additional *verifyStatus* interaction might help to limit certain incorrect interactions of the community pharmacist by disabling them in the interface. However, a multiplication of the number of interactions is not desirable, since nowadays we are confronted with a high amount of downtimes due to technical issues at the level of our national eHealth platform. The finding of these high unavailability rates, due to downtime of the national services, was first reported by Suykerbuyk et al. [5] when reporting about the perceptions of the patient about the national ePrescription.

Abstract. Ballistocardiography (BCG) has gained more attention due to the fundamental goal of medical intervention in diagnostics and follow-up. BCG is particularly suitable for the study of heart failure, which a recent study has shown. The results of this working group shall be validated and reproduced with another study trial. Therefore, acceleration sensor prototypes will be placed on various parts of the patient's body and be connected to a computer unit, which allows a high data quality and high signal resolution. A temporal shift of only 20 ns ensures real-time measurement of BCG parameters. The reference measurement will be done with a 12-channel ECG. The study will include patients with heart failure. All conducted tests take place as part of the diagnostic-therapeutic routine. The only change in the procedure concerns the additional equipment with the measuring sensors. The results will be the validation of the data from the other working group, as well as the information about the choice of sensors and clock frequency, the measuring points and the needed features for early detection of heart failure in BCG signals.

Keywords. Ballistocardiography, Seismocardiography, Heart Failure

1. Introduction

In recent years, the ballistocardiography has gained more attention [1–10], with the fundamental goal of medical intervention, for example, the diagnosis or follow-up.

However, ballistocardiography or seismocardiography [4,5] is particularly suitable for the study of heart failure (HF), as new studies confirm [10].

With the prospective study described here, the previous explorative results of the scientific society are to be reproduced, and this validates their validity.

¹ Corresponding Author, Nico Jähne-Raden, E-mail: Nico.Jaehne-Raden@plri.de.

The determination of the course of development of heart disease or long-term measurements of cardiac parameters are currently still difficult to implement and can only be determined with the help of medical visits or measurements of only 24 hours. However, there are diseases that have a much slower course or can appear at irregular intervals and are therefore unnoticed or measured within 24 hours.

Ballistocardiography should be a simple and inexpensive solution, but at the same time efficient and highly specialized [4,5,9,11,12]. Thus, it is possible to determine the blood pressure with the aid of the measured pulse transit time (time difference of the same signal between various measurement points on the subject's body), without the patient being awakened by inflating a cuff around the arm at night or interfering with his activities during the day, thereby distorting the result [13]. Since such a system is very small and has a battery with several days of running time, measurements of more than 24 hours (as a single measurement) can be made to reduce the disease deterioration of e.g. Cardiac insufficiency or high blood pressure (even over a longer period, for example, over months) [4,5].

At present, there are only a few ballistocardiographic measurements performed in everyday life or with cardiac patients. Data on the signal morphology of cardiac insufficiency have only been collected in an exploratory fashion [1]. With this prospective study planned, we then want to validate these exploratory results. Furthermore, in literature found setups raise further questions, so the technical measurement setup from the point of view of the working group is not optimal (choice of sensor, choice of clock frequency, choice of measurement position).

The overall objective of this prospective study is the validation of the results from the published results [10] for the measurement of ballistocardiographic or rather seismocardiographic signals in cardiac patients and their usability for heart failure diagnostics and/or course analysis, through the use of a highly specialized sensor measurement system consisting of body-worn acceleration sensor.

Secondary goal is to find out what features are needed for early detection of heart disease (e.g., Graph Similarity Score or other correlation) and what the signals of such diseases look like in a ballistocardiographic record.

2. Methods

The BCG sensor system is intended for the measurement. Components include the core unit, the FPGA processor board, and seven suitable triaxial acceleration sensors (Accelerometer). For the reference measurement, a 12-channel ECG is read out via the analog output parallel to the acceleration signals. This is a common method to be able to compare the two signals to each other and to provide information when in the BCG signal the characteristic features should appear.

The measuring system allows a high data quality (low signal-to-noise behavior) and a high signal resolution (2g scaling at 16 bit). In addition, an isochronous readout of the 3x7 position sensor channels at a suitable sample frequency can be realized. The sensor positions are 1x sternum, 2x cardiac apex – medio-clavicular (5. ICR), 1x torso, lateral le., 1x spine (7.-8. th), 1x A. temporalis le., and 1x A. radialis left-hand side. The aim of the used two-digit kilohertz range including oversampling is to ensure data robustness. A temporal shift of only 20 ns ensures real-time measurement of ballistocardiographic parameters.

The measurements are carried out simultaneously with the recordings of the general patient assessment. Participation in the study will not give subjects any further inconvenience with regards to additional assessment procedures (e.g., 6-minute-walking- test) or separate visits to the measurement environment. All conducted tests take place as part of the diagnostic-therapeutic routine. The only change in the procedure concerns the additional equipment with the measuring sensors.

The subject is initially in a stationary position during the measurement (for about one minute). Further, a six minutes gait phase, as is commonly done within the general clinical routine assessment, will follow. After this physical stress on the subjects, there is a five-minute recovery period. Conversations should be avoided during the measurement.

Figure 1. Model of the measure points.

The additional BCG sensor on the apex of the heart serves as a supplement to the first sensor since the electrode of the ECG is also attached to this position. This ensures a good recording of the acceleration at this.

Based on the hypothesis that there will be no subjects within the study population whose BCG/SCG signals differ fundamentally from the known morphology and the assumption that a homogeneous group exists under the given conditions more than 60 percent of the subjects have comparable features in the BCG or SCG signal, a rather small panel of subjects provides sufficient security for verification. In order to test the results of the difference between compensated and decompensated cardiac insufficiency subjects found in the literature see [10], 52 probands are needed with an effect size of 0.35. These subjects should be distributed as equally as possible to the four NYHA classes. In addition, the number of compensated and decompensated subjects should also be equally distributed.

3. Prospective Results

The main results of this study will be the validation of the data and results from the exploratory study with heart failure patients [10]. Hopefully, we are at least able to reproduce these results and give an overview of the performance of ballistocardiographic sensors in the diagnostics of cardiac patients. Moreover, we are confident to collect BCG or SCG signal data in the best quality state, so we can provide them to the scientific community soon as open data like it is requested by FAIR-principle. Those results will provide highly synchronous signal data with the best sample frequency we can reach (about 17 kHz) and the optimal entropy about the heart's movements and functions.

Another result of the performed measurements will be a deeper knowledge of the usability of specific digital triaxle acceleration sensors and other system specifics, like the clock frequency, to gain an optimal measurement result and furthermore, more knowledge about the measurement positions on a patient's body.

In the end, the ideal setup for those measurements is going to be presented. Moreover, the needed features for early detection of heart failure and the characteristics of the disease in BCG data will be shown and also the usability of this type of diagnostic for cardiac patients.

Addressing the Search Challenges of Precision Medicine with Information Retrieval Systems and Physician Readers

Kate Fultz HOLLIS^{a,1}, Kirk ROBERTS^b, Steven BEDRICK^a, William R. HERSH^a

^a*Oregon Health & Science University Department of Medical Informatics and Clinical Epidemiology, Portland, OR, USA*

^b*The University of Texas Health Science Center, School of Biomedical Informatics, Houston, TX, USA*

Abstract. The Text REtrieval Conference (TREC), co-sponsored by the National Institute of Standards and Technology (NIST) in the US and US Department of Defense, was started in 1992. TREC's purpose is to support research within the information retrieval community by providing the infrastructure necessary for large-scale evaluation of text retrieval methodologies. In 2017, the TREC Precision Medicine (Roberts et al., 2017) track grew from the Clinical Decision Support track and focused on a narrower problem domain of precision oncology. After three years of computer runs being evaluated for relevance by physician readers, we provide a unique perspective of how to evaluate computer-generated articles and clinical trials pulled from PubMed and Clinicaltrials.gov to find relevant information on medical cases.

Keywords. Precision medicine, information retrieval

1. Introduction

Starting in 2017, the Text REtrieval Conference (TREC), co-sponsored by the US National Institute of Standards and Technology (NIST) and the US Department of Defense, produces as part of its large information retrieval research program a project devoted to information retrieval focused on precision medicine. The 2017 “Overview of the TREC 2017 Precision Medicine Track” reported on search challenges with “precision medicine.” Many more treatment options become available with information tailored to the individual patient. The abundance of clinical information can easily overwhelm clinicians attempting to stay up to date with the latest findings and can easily inhibit a clinician's attempts to determine the best possible treatment for a particular patient. As a forerunner to the Precision Medicine Track, three consecutive years of the TREC Clinical Decision Support (CDS) track sought to evaluate information retrieval (IR) systems that provide medical evidence to the point-of-care. The CDS track then focused on the needs of precision medicine so IR systems can focus on this important issue [1].

The years 2017, 2018, and 2019 Precision Medicine Tracks focused on a single field, oncology, for a specific use case: genetic mutations of cancer. The main idea behind

¹ Corresponding Author, Kate Fultz Hollis; E-mail: fultzhol@ohsu.edu.

precision medicine is to use detailed patient information (largely genetic information in most current research) to identify the most effective treatments. Improving patient care in precision oncology then requires both (a) a mechanism to locate the latest research relevant to a patient, and (b) a fallback mechanism to locate the most relevant clinical trials when the latest techniques prove ineffective for a patient. In the first part, the track continues the previous Clinical Decision Support track [2], while in the second part the study expands the task to cover a new type of data (clinical trial descriptions). All of the TREC Precision Medicine tracks have used synthetic data to create topics of clinical cases for the computer search. All topics were created synthetically because it was difficult to obtain actual patient data for the project [3].

Detailed results from the TREC Precision Medicine Tracks are available in the overviews published on the TREC website. This paper focuses on the process of recruiting physicians to read the output from the computer runs, analyze the relevancy of the article or clinical trial for information about the topic, and help researchers provide information about the accuracy of the computer to find useful information for the physician.

2. Methods

A pooling strategy was used to determine the set of articles and trials to be judged. Slightly different pooling strategies were used for each year for each type of result, but the most common method is as follows. All articles and trials that were within the top 10 results for any research participant (i.e., the research groups searching for the article and clinical trial documents) were included in the pool. Additionally, a 10% sample of the results in position 11 to 100 were added to the pool. The pooled articles and clinical trials for each topic were judged by physicians who, in most cases, were graduates of the Oregon Health & Science University (OHSU) biomedical informatics graduate program. In the case of the clinical support track where physicians evaluated whether a clinical visit was relevant to the case, the challenges included terminology differences, negation, and time aspects having the most impact on retrieval inaccuracy. Edinger et al. describe in detail that these challenges also arise during cohort identification in medical text [4].

The cohort of graduates from OHSU ideally needed to have the following characteristics to become readers for the project: a certificate or master’s degree in biomedical informatics, a medical or doctor of osteopathic medicine degree to evaluate relevancy appropriate in a clinical situation, and an ability to quickly review many documents from a website created for the project. The number of topics (topic examples are in Table 1), documents found (total number of abstracts from PubMed and clinical trials from ClinicalTrials.gov), and readers for each year in the precision medicine track are outlined in Table 2.

Table 1. Example topics (3)

Disease	Variant	Demographic
melanoma	BRAF (V600E)	64-year-old male
melanoma	high serum LDH levels	69-year-old female
medullary thyroid cancer	RET	45-year-old female

Table 2. Number of topics, documents and readers

	2017	2018	2019
Number of Topics	30	50	40
Total Number of Documents	36081	36617	32162
Number of Physician Readers	18	26	19

2.1. Recruitment

Over three years of reader recruitment for the Precision Medicine track, we had to slightly change where we got readers for the project. In all three years, the chair of the OHSU Department of Medical Informatics and Clinical Epidemiology (DMICE) would send a letter to DMICE alumni roughly three months before the October 1 deadline. As the numbers in Table 2 indicate, we had many more topics in 2018 and so also sent the letter to chair people in other departments of biomedical informatics for their suggestions of clinical informatics fellows and doctorate students who might be interested in being readers for the project.

The incentives for readers to work on the project were to learn more about information retrieval and receive payment for reading. Noted in our recruitment letter for the work, we paid a set amount per hour. We paid for quantity of articles judged, not by time, but experience has shown that almost everyone can average one minute or less per article.

3. Results and discussion

The primary purpose for the physician readers in this project was to determine if each article and clinical trial found for a particular topic was 1) human medicine, 2) disease is relevant, partially relevant, or not relevant, 3) whether gene variants were discussed, and 4) whether the demographics (age and sex) matched (see figure 1 for screenshot of OHSU website for viewing articles and trials the computer selected). Details on the relevancy statistics for TREC Precision Medicine Tracks are in (1) and (2) and are forthcoming in 2019. The input of the physician readers has helped the project in many ways outlined in the following three years.

Figure 1. Example of OHSU website for reading articles captured in the computer runs.

3.1. 2017

The recruitment for readers began on August 17, 2017, and 18 readers finished 18 topics in 30 days. The remaining 12 topics were finished by October 8. In 2017, there were roughly 9% judged definitely relevant out of 22,642 literature articles, and 3% judged definitely relevant out of 13,441 clinical trials. We had and continue to have an international contingent of physician readers with many throughout the US and some in South America, Taiwan, and the Middle East. Readers mentioned that it was particularly difficult to find genes mentioned in the articles and usually would need to search in the full text of the article (the web interface we use shows article abstracts only). In terms of the web interface to read the abstracts and clinical trials, readers had, in some cases skipped articles and trials and had difficulty finding the particular missing article or trial in the web interface. Some of the time involved to get topics finished was due to skipped articles. By 2019, the website had been refined so that missing articles while working on the web interface was not a problem.

3.2. 2018

The second year of the Precision Medicine track included almost 50 topics, and it was necessary to recruit outside of the OHSU graduate program and in particular we found doctorate candidates in National Library of Medicine programs across the United States. The recruitment for readers began on August 22, 2018, and on average, 26 readers finished 25 topics in 21 days. The remaining 25 topics were finished by October 1. In 2018, there were roughly 15% judged definitely relevant out of 22,429 literature articles, and 6% judged definitely relevant out of 14,188 clinical trials. Readers from the doctorate programs would, in some cases, complete ranking topics faster than the physician readers and in other cases had the most questions and took more time. While we felt it was important to include informatics doctorate students without medical degrees, the physician readers had more skill in identifying articles and trials that would help for a particular topic.

3.3. 2019

At the time of this writing, the Precision Medicine Track reader analysis is still in operation (results due October 1, 2019). The recruitment for readers began on August 12, 2018, and on average 19 readers finished 19 topics in 16 days. The website took longer this year to produce, and there were more questions about how to match what the computer found as a genetic variant in articles and clinical trials.

The challenge with working with physician readers is that most have full-time clinical responsibilities (one reader was on call for forest fire duty in California in addition to clinical duties), but all readers were able to finish on time and in the case of two readers, one reading up to 1212 combined abstracts and trials for one topic in 10 days and another did four topics in 2 weeks. 15 readers in 2019 have made all of the previous Precision Medicine Tracks and look forward to working with us again. Many of the readers provide us with questions to help make the search for precision medicine topics better: e.g., the computer runs were sometimes not bringing in any relevant articles and how do the research groups change the algorithm to bring in more relevant articles

and trials. Some readers tried to do the reading and analysis on mobile devices. That is not possible now but could be considered in the future to enable more readers to work with the TREC website from OHSU DMICE.

It is possible that duplicate judging might improve the process as readers thought that in some cases, they were not as familiar with the case and suggested that another expert review their cases. We used to do duplicate judging (in the CDS Track) with kappa analysis, but the results always seemed to be about the same (good but not great consistency). While readers noted that there seemed to them poor relevancy of the articles and clinical trials chosen by computer, there appear to be improvements from 2017 to 2018, and there were fewer comments by readers about how few relevant articles there were in 2019 (only one reader and he was new).

The TREC assessment exercise can improve how we look for cases that closely resemble a clinical problem in precision medicine. The data from the physician readers has allowed more work on computer analysis of medical cases and eventually help with better searching for clinical cases in electronic health records.

4. Acknowledgements

KFH, KR, SB, and WTH and other organizers are grateful to the National Institute of Standards and Technology (NIST) for funding the assessment process for TREC.

Abstract. Digital Health is one of the three pillars for the effective implementation of Universal Health Coverage in Argentina. The Ministry of Health published the National Digital Health Strategy 2018-2024 in order to establish the conceptual guidelines for the design and development of interoperable health information systems as a state policy. The World Health Organization "National eHealth Strategy Toolkit", "Global Strategy on Digital Health" and other international and local evidence and expert recommendations were taken into account. The path to better healthcare involves adopting systems at the point of care, allowing for the primary recording of information and enabling information exchange through real interoperability. In that way, people, technology and processes will synergize to enhance integrated health service networks. In this paper, we describe the plan and the first two years of implementation of the strategy.

Keywords. eHealth, electronic health records, health information exchange, national health programs, health level seven, SNOMED.

1. Introduction

The United Nations have set universal healthcare coverage (UHC) as a target for sustainable development goal 3.8, to be achieved by 2030[1].

Only the appropriate use of digital technologies can enable the development of sustainable health systems that promote universal access to care. To deliver this potential, digital health initiatives must be guided by a robust strategy that integrates financial, organizational, human and technological resources [2]. History shows that ill-coordinated initiatives lead to vertical or stand-alone ICT solutions, that although well intended, often result in information fragmentation, and consequently poor delivery of care. Additionally, developing countries face specific challenges such as poor economics, political uncertainty, and the lack of cutting-edge infrastructure, that hampered the quality of healthcare [3].

Argentina has a complex federal healthcare system, where the national government, 24 jurisdictions and three subsystems interact: Public care, social security and private insurances. Many of its shortcomings come from its segmented and highly fragmented system, which also translates into the generation of information siloes. In many health centres in the country, health records are still kept in manual registries and logbooks. In a preliminary survey, at least 80% of the public healthcare facilities do not have

computers or Internet connection. This often results in duplication, over-reporting and underreporting for public health. To undertake this situation, in 2018 the Ministry of Health (MoH) promoted a National Digital Health Strategy, rising capacity building, engaging multiple stakeholders and promoting the development and interconnection of interoperable information systems, based on standards. This paper reflects the foundations and steps taken during the last two years to advance this mid and long term strategy.

2. Materials and Methods

2.1. Setting

Argentina is a Federal Republic subdivided into 24 jurisdictions, with an area of more than 1 million square miles and located in the southern half of South America. Its population is around 45 million people, unevenly distributed mainly in urban and suburban areas. Beyond the recurrent economic crises, it is an upper-middle-income country and has a developed healthcare system. However, health outcomes lag behind the country's potential, considering spending per capita of nearly 10 % of its gross domestic product. We have a mixed healthcare system with three components: public care, social security and private insurances. The social security subsystem is based on job taxes and covers 60% of the population, including active/retired workers and their families. Almost 2 million people (4%) pays for private insurance, leaving 36% (16 million people) with exclusive public care coverage based on jurisdictional states resources. There are significative gaps in morbidity and mortality outcomes between regions and subsystems. Since 2018, the National MoH has embraced an action plan to implement public health reform. Overall, the ultimate goal was to provide actual UHC by strengthening provincial health systems [4].

The existing fragmentation and segmentation of the healthcare system hamper the aggregation of patient data. Even though there is a need for digitalization, the creation of a single national health database is not possible given the political and health model. The incipient and progressive individual computerization of each system does not spontaneously solve this difficulty. Therefore, a distributed but interconnected health information ecosystem was selected as a feasible approach.

2.2. Methods

Our National Digital Health Strategy was built, taking into account international recommendations, like the World Health Organization toolkit for National eHealth Strategies, and their recent global strategy on digital health. We also participated in working groups such as HL7 International, SNOMED International and the Global Digital Health Partnership (GDHP). We capitalized regional initiatives like Information Systems for Health (IS4H) and RELACIS from the Pan American Health Organization (PAHO)[5], and Inter American Development Bank sponsored RACSEL. We interacted with Latin American leaders in charge of other national digital transformation experiences like Uruguayan SALUD.UY. Our approach is also grounded in the Principles for Digital Development and the subsequent Principles of Donor Alignment for Digital Health. These principles highlight the importance of supporting strong

national digital health strategies for sustainable country ownership, avoiding project overlap and fostering coordination and alignment of implementation activities [6].

However, it was essential to uphold the local existing resources and capacities, based on public, private and non-government organizations stakeholders who have been using Information Technologies for health services improvement for many years [7]. Moreover, the OECD has highlighted the ambitious general digital agenda and the efforts taking place in Argentina to digitalize and improve data governance in its public sector and build the foundations for a digital government [8].

3. Results

Through Resolution 189/2018, the highest health authority in Argentina settled the way forward to build, in collaboration with provincial governments and referents of the three subsystems, a network of information systems focused both on the population and individual health of each patient. The MoH created a National Directorate of Health Information System to coordinate such a strategy. It was essential to work on governance, making agreements with each province within the UHC framework plan.

The investments that each jurisdiction makes in its digitization projects are reinforced with national and international funds. Multilateral funding organizations (such as the World Bank and Inter American Development Bank) support projects like so-called SUMAR, which strengthen public health coverage to protect the most vulnerable populations [9]. Recently, they have included the Digital Health Strategy goals and will give economic incentives to the provinces that accomplish them for the next four years. As a result, every digital health transformation project should be aligned with the National Strategy. Additionally, the MoH got the funding for a National Connectivity Plan for public healthcare facilities. It will reach 2,000 remote primary care centres in the next two years, using satellite connections and optic fibre.

The Digital Health Strategy has two consecutive phases. Phase 1: Consensus, Infrastructure and Scalable Projects (2018-2019), which define the technical, regulatory and political foundations, with the participation of the community of experts and jurisdictions. Phase 2: Deepening, scaling up, and maturation (2020-2024) focuses on the adoption extension of the Digital Health tools and the functional enhancement of Information Systems. The priorities for the first stage were to:

Define interoperability standards: SNOMED, FHIR, ICD, etc.

Make the Central Infrastructure available: the enterprise service bus (EBS).

Identify and integrate the information needs: governance on the data flow.

Enhance local information systems: licensed, homegrown, or open-sourced.

Define the architecture to share clinical records, with HL7-FHIR.

Inform and empower the patient through a Citizen Health Portal (*Mi Argentina*).

Advance in the legal framework for digital health transformation.

Grow capacity building: train human resources in health information systems.

Argentina joined the SNOMED International Consortium in 2018. The National Release Centre has published three local extensions during the last 18 months, including medication codes to allow interoperable ePrescriptions. The MoH stated SNOMED as the clinical terminology standard for electronic health record (EHR) systems, leaving ICD for statistical and other administrative tasks. In addition, FHIR (Fast Healthcare

Interoperability Resources) [10] a next-generation standards framework created by HL7, was chosen as the standard for health care data exchange.

The National Digital Health Network was launched in April 2019, using an enterprise service bus technological infrastructure to connect different domains (EHR systems) across the country, as shown in Figure 1. We defined the required interoperability standards based on international recommendations and extensive local expertise in the field. By involving multiple stakeholders, we understood their views and gained their collaboration, support and endorsement of the strategy. A joint team including MoH, HL7 Argentina and Hospital Italiano (HIBA) experts developed the HL7-FHIR Enterprise Service Bus. The network enables the communication between domains but does not change the current processes of storage of health information. The data remains in each information system repository, and is only communicated to other domains when necessary (i.e. when the patient visit another clinic).

Figure 1. Simplified ESB architecture of the National Digital Health Network.

The MoH acquired RedHat OpenShift® licenses and services to support such infrastructure, hosted at the main Government Datacenter (ARSAT). The MoH team has been adopting this open-source container application platform based on the Kubernetes container orchestrator for enterprise application development and deployment, to guarantee the Health Network required availability and performance level.

After two years, every province (24) has defined its Digital Agenda for Health. Regarding their information systems, they have freely decided whether to acquire commercial EHR licenses, develop locally or adopt open-source software. There are advanced Projects in 16 of 24 states, where they selected pilot areas to carry out the digital transformation. Human resources, technology and processes were aligned to fulfil the project goals. Adopting a change management strategy was crucial for EHR implementations. The national MoH helped local teams to implement standards like SNOMED and FHIR in their systems. Vendors are progressively adopting standards to comply with National recommendations. Up to date, there are more than 2 million patients registered in the Network: it means that they have received care in an institution with interoperable EHR, and if they attend to another clinic, it would be possible to ask individually for such records through the network.

In collaboration with the Ministry of Modernisation, we launched a Citizen Health Portal. As of October 2019, more than 2 million users had been registered on the digital public service delivery platform *Mi Argentina*. It gives personal information like the Digital Vaccination Card, but also works as a patient privacy manager, to configure the opt-out consent for the information exchange trough the EBS health network.

We developed and implemented a National Telehealth Platform to perform eReferrals and eConsultations nationwide. It allows every clinician to interact with other healthcare professionals (specialists) using a personal computer or a mobile device in a secure environment, even if they do not have an EHR in place. As the Telehealth

Platform is connected to the National Enterprise Service Bus, different EHR can interoperate with it.

Besides the existing legal framework that rules Health IT implementations (Digital Signature, Personal Data Protection, EHR, etc.), the MoH dictated several resolutions to promote digitization while caring for privacy, confidentiality and security. In addition, there is a Digital Health Law project to be discussed at the Congress. Every jurisdiction can dictate their legal regulations, or endorse national laws.

We promoted several initiatives to enhance capacity building. In 2018 the MoH, PAHO and HIBA launched the “100 Leaders” Training Plan, using an online AMIA 10x10 course. There is also a monthly open course on standards and Conectathon, both onsite and online. We developed a basic online course on EHR fundamentals for more than 1,500 healthcare staff. The next big step is introducing these topics in healthcare professionals’ undergraduate curricula.

4. Conclusion

The Digital Health Strategy is not an end in itself but has the vision of reducing quality gaps in health care, implementing information systems that identify the characteristics and needs of the population, allowing longitudinal and comprehensive monitoring of people throughout the entire health system and providing innovative tools to health professionals and patients.

This paper underlines the role of the MoH in setting a National Digital Health Strategy for Argentina. Even though it has been a short period, since 2018, there have been several achievements that should be sustained. Besides its mid and long term planning, the strategy itself has to prove that it can succeed the time challenge of political transitions. Using international benchmarks and strategies like IS4H could be useful to support this initiative.

Assessing Opioid Use Patient Representations and Subtypes

Sarah MULLIN^{a,1} and Peter ELKIN^a

^a *University at Buffalo, Buffalo, NY, USA*

Abstract. Precision medicine, diagnosis, treatment, and prevention that accounts for natural human variability, can be beneficial for complex populations. The opioid user population is heterogeneous, characterized by many disorders, medications, and procedures. Using Electronic Health Record data, we create a patient representation, finding similarities between structured data, and then cluster the patients into patient subtypes. These subtypes can then be used for subsequent analysis.

Keywords. electronic health records, precision medicine, deep learning

1. Introduction

Health professionals are required to make analytic decisions influenced jointly by evidence-based medicine, prior practice knowledge, and specific patient attributes. Precision medicine aims to find appropriate treatments and diagnoses based on an individual patient since no method is ideal for every patient. Opioid-related adverse events and addiction are the main public health concern in the United States. Since 1999, more than 700,000 people have died from a drug overdose [8]. Partially due to over-prescribing and increased availability of potent synthetic opioids such as fentanyl, the opioid crisis has brought to light the need for finding better treatment options that are tailored to the patient for pain and addiction [7, 13].

Previous literature has demonstrated that high opioid dosage, concurrent use of sedative-hypnotics, substance abuse, and mental health comorbidities are associated with an increased risk of overdose [9]. Very few models have assessed the entire patient clinical picture and those that do focus mainly on medication data, require reliance on some sort of manual feature creation, and specifically are tasked to predict overdose [1; 5]. Therefore, characterizing an opioid prescribed population for specific pain treatment candidates, adverse opioid drug-drug interactions, and unknown risk factors for opioid overdose could be beneficial.

As a step toward precision medicine for an opioid prescribed population, using electronic health record data (EHR) provides the benefit of a large source of longitudinal data that encompasses the clinical picture with diagnoses, medications, and procedures. Retrospective observational data is especially useful for discovering unknown associations and can give a basis for finding similar patients [11]. However, EHR data suffers from an abundant amount of sparse attributes in the form of structured terminologically codified data and unstructured clinical text [10].

¹ Sarah Mullin, E-mail: sarahmul@buffalo.edu.

Deep learning advances have made it possible to incorporate high-dimensional data as input, as opposed to a select set of manually engineered features, by learning low dimensional dense embeddings [2, 6, 12]. Patient representations can be learned from neural networks that encode meaning and relationships into the dimensions. These patient vectors have been shown to increase predictive performance, assess patient similarity, and create patient subtypes [3, 14].

Using a paragraph vector model, we learn low dimensional dense patient representations from codified diagnoses, procedures, and medications for an opioid prescription population. To analyze these representations, we look at how well the vectors cluster patients into opioid user subtypes and known opioid misuse risk factors.

2. Methods

Two retrospective EHR databases, an outpatient practice and a hospital, were collected from January 2013 to December 2017 for patients who received an opioid prescription within the time frame. The data was approved as exempt research by the University at Buffalo IRB. Merger and de-identification of the data with assigned unique research identifiers were done with patient matching on social security number, date of birth, last name, and first three letters of the first name. Encounters for patients with a cancer diagnosis or those in palliative care were removed from the analysis. In order to assess the effects of opioid usage, patients were retained if they had at least two visits.

Due to the large volume of terminological codes and version differences across the time window, clinical classification software (CCS) was used to classify ICD-9 and ICD-10 diagnoses and current procedural terminology (CPT) codes to upper-level classes. Medications were mapped from national drug codes and local facility drug codes to the drug classes opioids, muscle relaxants, benzodiazepines, zolpidem, and Schedule II stimulants within the 2018 IBM® MarketScan® RED BOOK Database (www.ibm.com/Watson-Health/MarketScan). Finally, additional demographic variables, age at first opioid prescription, gender, race, ethnicity, and marital status were included. Race and ethnicity were standardized according to the Agency for Healthcare Research and Quality (AHRQ). Codes for drug overdose and adverse events, defined by ICD and manual review of clinical text, were removed from the patient representation for downstream prediction tasks.

To build the distributed representations of patients and their specific medical codes, we implemented the distributed bag of words algorithm (PV-DBOW) with 200-dimensional feature vectors and negative sampling [4]. Codes that were used less than two times in the analysis were removed. A patient vector consisted of all codes in temporal order by encounter date with randomization of medication, diagnosis, and procedure codes within an encounter. A temporal embedding was not considered due to the small patient sample in relation to deep learning methods. We trained the model for 500 epochs. To visualize our patient representations, we used t-distributed stochastic neighbour (t-SNE) embedding to collapse the representations into two dimensions. Cosine similarity, a simple mean of the projection weight vectors, is used to assess similar codes. Finally, we used k-means with Euclidean distance to create patient subtypes from the patient representations and assessed the distribution of features within those groupings.

3. Results

After removal of patients with cancer and palliative care diagnoses, the patient representation was trained on 3,986 patients. The features consisted of 129 distinct procedural CCS codes, 44 distinct medication codes, 256 distinct diagnostic CCS codes, and four demographic variables. For diagnostic codes, ‘residual codes; unclassified,’ ‘medical examination/evaluation,’ and ‘administrative/social admission’ were removed. 13% of patients had a diagnostic code for opioid dependence, with 11.4% on buprenorphine treatment and 4.1% on methadone treatment. Opioid-related adverse events and overdoses made up only 3.6% of cases. Mental health-related diagnoses were recorded in 60% of the population, and non-opioid substance abuse was recorded in 8.1% of the population. Analysing the demographic features of the cohort, 64% were female, 58.8% were White, 40.14% were Black, and 3.7% were Hispanic. On average, there were 29 codes per patient.

Cosine similarity was assessed between the codes in the embedding (Table 1). Opioid medication codes, psychological and mood disorder codes, and procedures relating to pain were similar, implying the associations of previously reported risk factors in an opioid-related population are being learned by the distributed representation.

Table 1. Validation examples of patient representation code embeddings measured by cosine similarity. (p) indicates CCS procedure code as opposed to diagnosis code.

Code	1 st Similar (cosine similarity)	2 nd Similar (cosine similarity)	3 rd Similar (cosine similarity)	4 th Similar (cosine similarity)
Methadone	CCS 211: Other connective tissue disease (0.59)	Morphine Long-Acting (0.57)	CCS 204: Other non-traumatic joint disorders (0.56)	Hydromorphone Short-Acting (0.53)
CCS 651: Anxiety disorders	CCS 661: Substance-related disorders (0.67)	CCS 663: History of mental health and substance abuse codes (0.65)	CCS 652: Malaise and fatigue (0.62)	CCS 657: Mood Disorders (0.61)
CCS(p) 155: Arthrocentesis	CCS(p) 173: Diagnostic procedures on skin and subcutaneous tissue (0.40)	CCS(p) 38: Diagnostic procedures on lung and bronchus (0.34)	Tramadol Long-Acting (0.27)	Orphenadrine (0.25)

Visualizing our patient representations, we see that opioid abuse, misuse, and poisoning, opioid dependence, mental illnesses, and other drug abuse are not well represented in two dimensions of the embeddings (Figure 1).

Figure 1. T-SNE patient representations of opioid-related outcomes misuse and dependence and other risk factors, drug abuse and mental health.

Using the elbow method and distortion, 8 clusters were found to be optimal for k-means clustering. Compressing the data into two dimensions using t-SNE, the clusters were plotted for visual inspection (Figure 2). The clusters have well-distinguished groupings. Cluster 6 is characterized by opioid dependence (58%) and opioid poisonings and misuse (44%). Cluster 0 has a high proportion of hydrocodone, fentanyl, and nutritional disorders. Cluster 1 has a high proportion of buprenorphine users, benzodiazepines, and mental health disorders, particularly substance-related disorders, anxiety, and mood disorders. Cluster 2 has a high proportion of opioid users related to bone and tissue diseases and spine and back pain. Cluster 3 is characterized by joint and nervous system disorders, muscle relaxers, and hydrocodone or buprenorphine use. Cluster 4 is also characterized by connective tissue and joint disorders, but patients are primarily on tramadol or hydrocodone. Cluster 5 is characterized by urinary infections and disorders and arthrocentesis. Cluster 7 is characterized by hypertension, diabetes, and gastrointestinal disorders.

Figure 2. K-means clusters using t-SNE dimensions for opioid prescribed patient population.

4. Discussion and Conclusion

Patient subtyping, seeking similar groups of people in an opioid patient population with different diagnostic, medication, and procedural patterns, is important to address the heterogeneity in patients and to find potential new treatments or treatment plans. By learning a patient representation of EHR codes as opposed to primarily manually featured engineered features, we can learn new risk factors for predicting multiple tasks, including opioid misuse, in a general and overly complex cohort of opioid users.

Shown in the k-means clusters, patient representations can be grouped into subtypes that can be beneficial to individual treatment plans and policymakers for complex patient populations.

Automated Engineering for Health Smart Homes: Find a Way in the Jungle of Assistance Systems

Bastian WOLLSCHLAEGER ^{a,1} and Klaus KABITZSCH ^a

^aChair of Technical Information Systems, Technische Universität Dresden, 01062 Dresden, Germany

Abstract. Health Smart Homes are a promising part of digital personalized health care. However, engineering of the underlying residential assistance systems is a complex process that needs to be supported by computer-based design tools. This paper presents a formal definition for the engineering task and proposes a methodology for model-driven design process automation, that is implemented in a web-based pilot application. Using this approach for design support, the challenge to efficiently compose personalized assistance systems for patients can be coped with in the future, which reduces a major barrier for smart home assistance applications.

Keywords. Ambient Assisted Living, Health Smart Home, Digital Personalized Health, Interoperability, Telemedicine, Telehealth

1. Introduction

As a promising part of digital personalized health care, *Health Smart Homes* (HSH) [1,2] combine concepts from Smart Home, Ambient Assisted Living (AAL), and Telemedicine [3], aiming to improve the quality of health care delivery [4,5]. Yet, a significant proliferation of HSH technology into real-world applications is still missing [6,7], largely due to ineffectiveness of system design [8]. The range of available assistance components is overwhelming and these components are not always compatible with each other [4,9]. Even professional planners are not able to chart the area of assistance solutions comprehensively, as they can only be familiar with a small number of components. Thus, engineers, patients and health care providers are tangled up in navigating the confusing “jungle” of assistance solutions. They require support for component selection and composition in order to tailor assistance systems to patient needs.

We envision an automated design approach that takes patient requirements and needs into account and identifies several suggestions that each fulfill the patient’s individual demand for technical support [9]. As a prerequisite for this vision, this paper presents a formal definition for the engineering task and proposes a methodology for model-driven design process automation.

¹Corresponding author, e-mail: bastian.wollschlaeger@tu-dresden.de.

The remainder of the paper is structured as follows: The next section infers requirements for a design methodology and discusses related work for HSH engineering. The proposed new methodology is presented in Section 3, after introducing a formal problem definition for the engineering task. Section 4 discusses the methodology based on a pilot application. Finally, Section 5 summarizes the paper and provides further research areas.

2. Related Work

A design methodology needs to meet the following requirements: *Req. A) Efficiency and Sustainability* allows the methodology to incorporate the re-use of existing components. *Req. B) Allowing for individual Customizability* states that fine-grained customization capabilities are required [1, 10]. Since manually exploring the design space is not feasible due to a large number of potential solutions, *Req. C) Capability of Automation* demands the automation of key processing steps of the design methodology. Considering the variety of possible solutions, determining the most suitable solution will involve multiple criteria (such as costs, installation and maintenance effort). Thus, *Req. D) Multiple Solutions* states that a design methodology needs to be able to offer a "design space" containing possible alternative designs [11].

Nowadays, HSH systems are often developed from scratch as monolithic systems (*one-off approach*) [6, 12], applying generic high-level methodologies such as model-driven approaches (MDA). While this allows for a precise customization, these approaches become inefficient [11] as they incur an high effort for system design. Alternatively, HSH are sometimes designed based on coarse-grain bundles of existing modular components (*bundle approach*) [10], in an attempt to achieve a rudimentary level of customization with lower design effort. However, given the diversity of assistance solutions [9], the bundle approach does not allow a sufficiently fine-grained customization. *Integration-focused approaches* rely on standardization of data exchange, integration frameworks or plug-and-play mechanisms when composing systems from components-off-the-shelf [6]. Yet, while this reduces interoperability issues [1], selection of components and communication planning still needs to be done manually.

As a consequence, there is a need for a new methodology that is capable of fulfilling *Req. A) to D)*, especially providing individual customization capabilities in combination with an efficient design approach.

3. Automated Engineering of Health Smart Homes

3.1. Formal Task Definition

The task in HSH engineering is to design a suitable assistance system by selecting and composing assistance components to *Candidate Solutions* HSH_{cand} in order to meet the set of requirements posed by the HSH occupant (*Condition Portfolio* HSH_{req}). The design process builds upon a *Knowledge Base* HSH_{KB} containing the vocabularies of user requirements, assistance functions and assistance components [13] as well as their interdependencies. This task description can be formalized as follows:

Definition 1 Knowledge Base: Let be: (i) \hat{R} the universal set of user requirements; (ii) \hat{F} the universal set of assistance functionality; (iii) \hat{C} the universal set of assistance components; (iv) \hat{T} the universal set of semantic types of the information exchangeable by assistance components; (v) $R_f \subseteq \hat{R}$ the set of user requirements satisfied by each assistance functionality $f \in \hat{F}$; (vi) $F_c \subseteq \hat{F}$ one set of realized assistance functions for each assistance component $c \in \hat{C}$; (vii) then the knowledge base for HSH design is defined as $HSH_{KB} = (\hat{R}, \hat{F}, \hat{C}, \hat{T}, \cup R_f, \cup F_c)$ ².

Definition 2 Condition Portfolio: The patient's condition portfolio is defined as a subset R of user requirements s. t. $HSH_{req} = R \subseteq \hat{R}$.

Definition 3 Candidate Solution: Let be: (i) C the multi set of selected assistance components, with $\forall c \in C : c \in \hat{C}$; (ii) B the multi set of bindings (i. e. communication relations) modeling the information exchange between assistance components, with each binding $b = (c_o, c_i, T) \in B$ defined by the tuple of the information output and input components c_o and c_i , and the set $T \subseteq \hat{T}$ of information types of the exchanged data; (iii) then a candidate solution of a HSH is defined as $HSH_{cand} = (C, B)$.

Definition 4 HSH Engineering Task: Given the input of: (i) HSH_{KB} a knowledge base for HSH engineering and (ii) HSH_{req} a specific patient condition portfolio, the goal of the HSH engineering task is to find the set \mathcal{C} of valid candidate solutions HSH_{cand} with validity of a candidate solution $HSH_{cand} = (C, B) \in \mathcal{C}$ meaning that all patient requirements are met by the candidate solution: $R \subseteq \cup_{c \in C} \cup_{f \in F_c} R_f$.

3.2. Engineering Methodology for Health Smart Homes

Following the MDA paradigm to abstract from technology-specific information, we propose to add an additional technology-independent intermediate layer. As can be seen from the equation in Def. 4, when determining the validity of the candidate solutions, an intermediate step is taken to relate assistance components C to the requirements R . In accordance to this observation, a suitable intermediate model layer consists of an information flow graph containing technology-independent assistance functions F :

Definition 5 HSH System Specification: Let be: (i) F the multi set of required assistance functionality, with $\forall f \in F : f \in \hat{F}$; (ii) L the multi set of links modeling the information exchange between assistance functions, with each link $l = (f_o, f_i, T) \in L$ defined by the tuple of the information output and input functions f_o and f_i , and the set $T \subseteq \hat{T}$ of abstract information types of the exchanged information; (iii) then a system specification for HSH is defined as $HSH_{spec} = (F, L)$.

With the introduction of the intermediate model layer HSH_{spec} , the design task can be split into *Step 1) Computation of HSH system specification*, which yields technology- and vendor-neutral formalized specifications for the HSH, and *Step 2) Materializing the specification with assistance components*, which in turn yields several design suggestions (Figure 1). The different design alternatives may now be inspected in order to determine the most promising design proposition. As this depends on planner's experience and

²For readability we do not write the index for unions/sums that are unambiguous, i. e. $\cup F_c = \cup_{c \in \hat{C}} F_c$.

Figure 1. HSH engineering task and methodology of Automated Design for HSH

involves assessing additional criteria (e. g. costs) not modeled here and the decision may be rooted in the planner's experience, making the final decision is out of scope of this methodology and needs to be made in close collaboration with the patient.

4. Prototype and Discussion

To show the feasibility of the methodology, a pilot application has been implemented as a web-based suggestion system for AAL counselors, intended to facilitate the design and tailoring process of HSH solutions during patient consultation. After an interview-style analysis of user requirements, appropriate assistance functionality is determined. Finally, suitable assistance components are suggested to the AAL counselor and patient.

By composing existing assistance components based on their functionality, the presented methodology is able to efficiently provide several system proposals without the need for labor-intensively developing assistance systems from scratch. It therefore meets *Req. A) Efficiency and Sustainability*. Since the methodology is based on formal sets of user requirements, assistance functions and assistance component functionality, it can be supported by computer-based tools, fulfilling *Req. C) Capability of Automation*. The application of computer-based tools furthermore allows for an efficient exploration of the design space. The methodology is thus able to meet *Req. D) Multiple Solutions*. Finally, the input for the proposed design process is not confined to a fixed set of coarse patient types, but rather features a detailed vocabulary \hat{R} of possible user requirements and patient conditions, which in the pilot application have been identified according to personas and insights of health care providers. Thus, a fine-grained customization of the assistance systems is possible, fulfilling *Req. B) Allowing for individual Customizability*. Compared to the engineering methods *one-off* and *bundle* approach discussed in Section 2, the proposed methodology allows for an efficient exploration of the design space, thus lowering the overall costs of HSH engineering. Subsequently, *integration-focused* approaches can be applied for realization of the selected system design.

5. Conclusion

One major barrier for the proliferation of assistance systems in the context of smart homes is the tedious and ineffective design process. This paper proposed a model-based methodology for the automated engineering of HSH, enabling re-use of existing assistance components as well as fine-grained customization of the resulting assistance sys-

tems. By splitting the design task introducing a technology-neutral intermediate layer for system specification, the overall engineering task becomes more manageable and an abstraction from technology-specific information can be achieved.

Next steps include a further investigation into functional component models to ensure that the broad variety of real-world assistance functionality can be adequately modeled. Similarly, refining the universal set \hat{R} as well as optimizing the algorithm for design candidate identification are important tasks. Finally, tool-support for the actual process of functional component modeling shall reduce the impediments for component manufacturers to provide high-quality functional component models.

Acknowledgements

The work for this paper was funded by the European Social Fund and the Free State of Saxony (Grant no. 100310385). The authors would also like to offer special thanks to Tuan Linh Mai as well as Lena Otto for their valuable feedback on the manuscript.

Decreasing Number of Medication Prescriptions After e-Prescriptions Became Mandatory and Their Valid Period Was Extended: A Big Bang Policy Change in Finland in 2017

^c*Social Insurance Institution of Finland (Kela), Helsinki, Finland*

Abstract. We measured the first time the number of prescriptions in Finland by using a centralized national shared repository of e-prescriptions and their dispensing data. This was made possible by introducing two policy interventions that were effective since 1 January 2017: mandatory e-prescribing and extension of a prescription's valid period from 12 months to two years. The trend in recording e-prescriptions started decreasing since the 'big bang', but pharmacy dispensations were not affected, as followed up to September 2019. It is possible to monitor the effects of health policy interventions by utilizing national e-health data systems, especially at the occurrence of a natural experiment.

Keywords. Electronic prescribing, large-scale interventions, health policy analysis, national data repositories, eHealth, Kanta services, Finland

1. Introduction

Successful nationwide e-health services, such as electronic prescription service, across different health systems in various countries or regions, can provide valuable information for authorities that have yet to launch these services [1,2].

In Finland, implementation and adoption of the national Kanta services have been carried out in phases step-by-step since May 2010 [3]. Electronic prescriptions (e-prescriptions) are part of the national data system services for healthcare, pharmacies, citizens and social welfare service providers. A fully operational and nationwide shared Prescription Centre has been mandated by law to be implemented in all community pharmacies (2012), in public healthcare (2013), and private healthcare (2015). Finnish community pharmacies started to dispense e-prescriptions in 2012. A web service for physicians and dentists for the issuing of e-prescriptions (Kelain) was launched in

¹ Corresponding Author, Vesa Jormanainen, Social and Health Systems Research, Finnish Institute for Health and Welfare, P.O. Box 30, 00271 Helsinki, Finland; E-mail: vesa.jormanainen@thl.fi.

September 2016. First, in Europe, Finnish citizens could use their e-prescriptions to purchase medication that is dispensed in Estonia (since January 2019) and Croatia (since June 2019).

In the 2007 e-health roadmap [4], Finland chose to ensure the availability of information for patients undergoing treatment, regardless of time and place, in both public and private healthcare. Second, Finland chose to enable the participation of citizens and patients and to ensure that citizens have access to more information, including high-quality health information. These strategic choices are also reflected in the decisions to introduce the national e-prescription system, Prescription Centre, and citizens' access to their health data and e-prescriptions in May 2010.

Finland is a sparsely populated country of 5.5 million inhabitants. In the eastern and northern parts of the country, the population density is especially low, and distances are long. A large number of small municipalities have big responsibilities that include providing both healthcare and social welfare services, which is a unique characteristic of the Finnish healthcare and social welfare system [5,6]. The Finnish health system is highly decentralized and performs rather well, with users expressing comparatively high levels of satisfaction with the quality of services.

Patients are offered access to their health data on a national level only in few countries, such as Australia, Canada, Denmark, Estonia, Finland, France, Iceland, New Zealand, Norway, Scotland, Singapore and Sweden [7]. In Finland, community pharmacy customers are familiar and very satisfied with the national e-health service for viewing their e-prescriptions [8,9]. General practitioners in Finland report that e-prescribing has improved their patient medication management [10,11]. By introducing a nationwide e-prescription and a centralized shared Prescription Centre, Finnish citizens are provided with direct online access to their complete prescription data.

The introduction of a mandatory e-prescribing did not come as a surprise to healthcare actors in Finland. It was discussed lively during Parliament committee hearings in early spring 2014 when Parliament accepted a two-stage introduction of the mandatory e-prescription for the private sector. Since 2017, all public and most private healthcare providers have subscribed and use the Prescription Centre's services. At the same time, the valid period of a prescription was extended to two years.

The administrative nationwide 'big bang' change of 1 January 2017 was essentially constructed on top of a 'blueprint' plan. These large-scale healthcare changes provided us with the first opportunity to measure prescription volume in Finland, and how healthcare professionals (physicians and dentists) learn to use new ways to issue e-prescriptions in their care and cure processes.

2. Material and Method

The Prescription Centre is a national centralized and shared repository of e-prescriptions and their dispensing data. Since January 2017, community pharmacies record paper or telephone prescriptions into the repository (100% coverage).

We extracted prospective monthly indicator data in aggregate form from May 2010 to September 2019. Based on numbers of medication dispensations at community pharmacies in the Finnish Statistics on Medicines, it is estimated that Prescription Centre data was 90% complete in 2015, 95% complete in 2016 and 100% complete after that. Variation in monthly numbers of e-prescriptions and their dispensing events was

smoothed by using a 3-month moving average. In annual calculations of number of persons, one personal identification code was included only once.

3. Results

Totally 162.90 million (M) e-prescriptions and 297.15M dispensations were recorded into the Prescription Centre from May 2010 to December 2018. Altogether 4.34M persons received an e-prescription in 2017 and 4.38M in 2018.

3.1. Medication dispensations in 2015–2019

Numbers of dispensations from e-prescriptions were 49.03M in 2015 (90% coverage; estimate corrected as 54.48M), 55.12M in 2016 (95% coverage; estimate corrected as 58.12M), 61.39M in 2017 and 64.42M in 2018. An estimated corresponding figure in 2019 would be 65.82M. Monthly numbers of dispensations in community pharmacies in Finland, smoothed by using a 3-month moving average, are presented in Figure 1. The trend curve shows an overall increasing time series, and some signs according to which monthly dispensation number vary on average 5.5M dispensations per month.

Figure 1. Monthly time series of dispensing events and e-prescriptions from the national Prescription Centre service launch in May 2010 to September 2019 in Finland.

3.2. E-Prescriptions in 2015–2019

Numbers of e-prescriptions were 27.93M in 2015 (if 90% coverage, corrected as 31.03M), 29.61M in 2016 (if 95% coverage, corrected as 32.90M), 31.91M in 2017 and 28.29M in 2018. An estimated corresponding figure in 2019 would be 29.13 M. Annual numbers of recorded e-prescriptions present an increasing trend in 2015–2016, given estimates for 2015–2016 were correct, and a decreasing trend in 2017–2019, given that

the estimate for 2019 was correct. Monthly numbers of recorded e-prescriptions into the national Prescription Centre trend curve shows an overall increasing time series for 2015–2016 and an overall decreasing time series for 2017 onwards (Figure 1). The trend curve also describes an annual decrease of e-prescription recordings in June–July, common summer holiday months in Finland.

3.3. Paper and telephone e-prescriptions in 2017–2018

Numbers of paper and telephone prescriptions recorded at the community pharmacies were 0.404M in 2017 (1.26% of all prescriptions) and 0.384M in 2018 (1.23%). The numbers were highest (on average 37,000 per month) in the first quarter of 2017 but decreased towards end-2018 being on average 31,000 per month during the last quarter in 2018. During 2017–2018, a third of the prescriptions recorded at pharmacies were issued via telephone and two-thirds were paper prescriptions. If one issues a paper or telephone prescription, the reason for action must be recorded. Legal categories include a technical system failure (80% of the reasons) and an emergent need for medication (12.5% on average). The other reasons' proportion decreased from 10% in 2017 to 5% in 2018.

3.4. E-Prescriptions via Kelain web service in 2016–2019

The Kelain web service was launched in September 2016. Using Kelain, the number of e-prescriptions issued was 0.020M in 2016, whereas 0.322M in 2017 and 0.301M in 2018. Monthly numbers rose rapidly to 25,000–30,000 but have since decreased to current 20,000–25,000 level. Comparing numbers of paper prescriptions recorded at pharmacies to those of Kelain web service, it seems that Kelain has taken volumes from paper prescriptions in general. The number of registered Kelain users rose rapidly from 10,000 in early-2017 to current 18,600 in September 2019. The latest number is approximately 50% of the physicians and dentists in Finland.

4. Discussion and Conclusions

We measured the first time number of prescriptions in Finland in 2017 by using national e-health data systems (e.g., Prescription Centre). We were also able to monitor the effects of two simultaneously introduced policy interventions, mandatory use of e-prescribing and extension of a prescription's valid period for up to two years. The trend in recording e-prescriptions decreased since the 'big bang', but pharmacy dispensations were not affected, and this followed up to September 2019.

From a clinician's point of view, e-prescription has brought several welcomed changes. The extended 2-year valid period has reduced amounts of prescription renewals, especially among patients reviewed to be in a stable state, such as steady hypertension. In general, e-prescription is seen as a valuable asset among clinician peers. Physicians can check all the patient's prescriptions through Kanta, and several electronic patient record (EPR) systems are also able to search for and inform the physician on drug interactions otherwise overlooked. The most common complaint heard among peers is that sometimes renewing prescriptions is a labour-intensive process. However, this process varies between EPRs' process designs. Citizens' access to their e-prescriptions

via national My Kanta Pages has also brought possibility for patients to send prescription renewal requests straight to physicians with no accessory contact to their respective healthcare site. With known patients, this reduces the amount of work for a physician. As a downside, this also allows patients to request renewals of prescriptions that are meant for short-term use or prescriptions that require contact to a physician, such as antibiotics, corticosteroids or central nervous system medication. Prescription renewal requests are usually directed to public primary healthcare which may require additional work to be done there.

Large-scale changes (such as described in this paper) allow, at least in theory, for dealing with interrelated elements of a policy. However, such reforms are rare [12]. The outcomes of policy reforms depend on the integration of scale and pace, the intersection of which yields basically four possibilities: rapid enactment of large-scale change ('a big bang'), step-wise enactment of large-scale change ('a blueprint'), rapid enactment of multiple small-scale changes ('a mosaic') or piecemeal enactment of small-scale changes over time (incrementalism). In our case, we first introduced a step-wise enactment of a large-scale change by introducing e-prescription and national Prescription Centre services. In the second stage, based on the results of the implementation, adoption and large-scale use of the Prescription Centre, we were able to change healthcare system and professionals to start using e-prescriptions all over Finland since one date (1 January 2017).

In conclusion, it is possible to introduce large-scale, national, centralized, integrated and shared e-prescription service that is implemented and widely in sustainable use in a country. Full e-prescription coverage (100%) can be used to monitor and evaluate various medication interventions or administrative changes in real-time.

Exploratory Analysis of HIV Status Knowledge and Associated Factors Using Data from Electronic Medical Records

Natividad BURDISO^{a,1}, Santiago ESTEBAN^a, Karin S. KOPITOWSKI^a and Sergio A. TERRASA^a

^a Family and Community Division, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Abstract. Despite recommendations for the routine HIV testing of all sexually active individuals, a significant percentage of HIV-positive adults are unaware of their HIV status. Therefore, a number of strategies have been implemented to expand HIV testing, which in turn makes it necessary to develop tools for identifying patients with unknown HIV status. This study presents the results of an external validation of an electronic phenotyping algorithm for identifying HIV status and its application on a retrospective cohort in order to explore temporal trends of HIV knowledge status and associated factors.

Keywords. HIV, universal HIV testing, electronic phenotyping algorithm, external validation

1. Introduction

The early detection and treatment of human immunodeficiency virus (HIV) infection in its early stages has been shown to have a number of benefits at the both the individual and social level, not only because it decreases the risk of progression to acquired immunodeficiency syndrome (AIDS), but also because it diminishes the risk of sexual and perinatal transmission[1]. Based on these findings, the U.S Preventive Service Task and Force (USPSTF) recommends that clinicians test patients aged 15 to 65 years for HIV infection, as well as all pregnant women regardless of age, whether or not behavioural risk factors have been reported[6]. Nonetheless, a significant percentage of HIV-positive adults are unaware of their HIV status (18% internationally and 30% within Argentina) [3]. Thus, a number of methods have been developed to detect patients with unknown HIV status. Although self-report has been widely used, the validity of this method has been called into question given that patients may not recall whether or not they have previously been tested[5]. Therefore, alternative methods based on information available in clinical records have been designed. Nonetheless, although electronic medical records (EMRs) facilitate the search for HIV-positive patients, who tend to be easily identifiable through laboratory data, the identification of patients with unknown HIV status is more complex since there is currently no reliable method for assigning a patient to that category. Accordingly, unknown HIV status should be inferred from the

¹Corresponding Author, E-mail: natividad.burdisso@hospitalitaliano.org.ar

absence of information identifying a patient as HIV-positive or HIV-negative. Based on this assumption, Felsen et al. [4] developed a rule-based algorithm for electronic phenotyping based on electronic medical records in order to classify patients by their HIV status. The algorithm's accuracy for identifying patients with unknown HIV status was assessed by comparing the results to a manual review. Its sensitivity and specificity were 99.4% (95% CI: 96.5-100%) and 95.2% (95% CI: 83.8-99.4%) respectively. Despite the fact that the development of EMR-based algorithms has become popular in recent years, their external validation – that is, their application to populations other than those they were initially developed for – is far less common [7]. Thus, we decided to externally validate the algorithm developed by Felsen et al. using data obtained from the EMR at Hospital Italiano de Buenos Aires (HIBA) and apply it to a cohort of patients to explore the temporal trends of HIV status knowledge change and associated factors. The two main aims of our study are 1) To locally validate the EMR-based phenotyping algorithm for identifying HIV status developed by Felsen et al. and 2) To describe the trends over time in the percentage of individuals who know their HIV status among patients enrolled in the health insurance plan at HIBA and explore the relationship between HIV knowledge status change, sex, age and year of enrollment.

2. Methods

For the validation of the phenotyping algorithm, two types of variables were included: 1) standardized codes linked to HIV/AIDS (used at inpatient, outpatient, and emergency department facilities); and 2) laboratory data such as anti-HIV antibodies, western blot, viral load, and CD4 cell count. No free-text data was used. The algorithm is shown in figure 1.

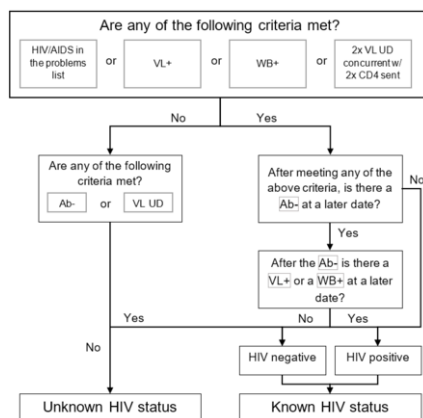

Figure 1. HIV status classification algorithm. VL: Viral load; WB: Western Blot; UD: undetectable; Ab: ELISA antibody test.

Manual chart review was defined as the reference standard. Two family physicians analyzed all of the data available in the EMR of each patient. The criteria for classifying patients according to their HIV status were as follows: HIV-positive: presence of a positive WB, detectable VL, documented HIV infection by a provider, prescription of antiretroviral therapy, or mention of infection in narrative text notes; HIV-negative: does not meet criteria for HIV-positive, and the presence of a negative western blot or ELISA

test for anti-HIV antibodies; Unknown HIV status: does not meet criteria for HIV-positive or HIV-negative. Assuming that our algorithm would have a sensibility of 99% and a specificity of 95.2% – as in Felsen et al. (2014) – a sample size of 300 observations was estimated in order to obtain a margin of error of $\pm 0.75\%$ on a 95% confidence interval in our test set.

For the assessment of HIV status temporal trends, we applied the algorithm to all the patients enrolled in the insurance plan at the HIBA for at least 12 months aged 15 to 65 between 1/1/2008 and 31/12/2015, every year at the last day of the year. We measured the percentage of HIV status knowledge both per year and cumulative. We also assessed the percentage of patients that changed their status over time. Lastly, using a three year follow up sub-cohort of yearly newly enrolled patients (assuming their status before enrolment was ‘unknown’), we assessed the time until status change using a cox proportional hazards model which allowed us to explore its association with sex, age and cohort entry year. All statistical analyses were computed using R.

3. Results

When applied to our test set, the algorithm showed similar metrics to those reports by the authors [sensitivity 97.25% (92.16 - 99.42); specificity 100% (98.08 - 100), positive predictive value 100% (97 - 100) and negative predictive value 98.45% (96 - 100)]. regarding HIV knowledge status trends, as it is shown in table 2, ‘known’ HIV status (positive + negative results) percentage has been increasing since 2008, mostly due to an increasing percentage of negative tests, at a mean increase of 0.6% per year. HIV knowledge status change (from ‘unknown’ to ‘known’) appears to be in an upward trend since 2013, which coincides with the initial USPSTF recommendation (figure 2). This trend seems to be led by young adults (20 – 40 years old). Upon visual inspection of the trends between sexes, a higher percentage of women have changed their status to ‘known’, although men show a steeper curve since 2013.

Table 2. Patients’ description and HIV knowledge status.

Year	n	Sex - Female (%)	Age (median [IQR])	Known status – Negative (%)	Known status – Positive (%)	Unknown status (%)	At least one HIV test since 2008 (%)	Newly enrolled (%)
2008	89481	49340 (55.1)	40.00 [29.00, 54.00]	6164 (6.9)	234 (0.3)	83083 (92.8)	19082 (21.3)	11352 (12.7)

		50167	41.00	7228	160	81701	25591	9966
2012	89089	50291 (56.3)	42.00 [31.00, 55.00]	7761 (8.1)	161 (0.2)	81618 (91.7)	27498 (28.7)	8028 (11.2)
		50291	42.00	7761	161	81618	27498	8028
2013	89540	49773 (56.2)	42.00 [31.00, 55.00]	8726 (8.7)	150 (0.2)	80204 (91.2)	29591 (30.7)	7139 (9.0)
		49773	42.00	8726	150	80204	29591	7139
2014	89080	49527 (55.9)	42.00 [31.00, 55.00]	9981 (9.8)	155 (0.2)	78936 (90.0)	32321 (33.2)	7257 (8.0)
		49527	42.00	9981	155	78936	32321	7257
2015	89072	(55.6)	[31.00, 54.00]	(11.2)	(0.2)	(88.6)	(36.3)	(8.1)

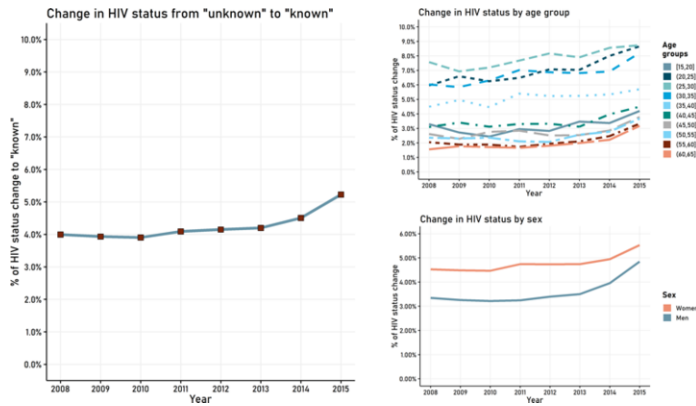

Figure 2. HIV knowledge status change.

Figure 3 and 4 show a clear and independent association between sex, age, cohort entry year and time until status change. Cohort entry year shows to be strongly associated with a higher proportion of patients who changed their status from ‘unknown’ to ‘known’ after the three years of follow up. This association seems stronger for every year compared with 2008, as is shown by the increasing hazard ratios.

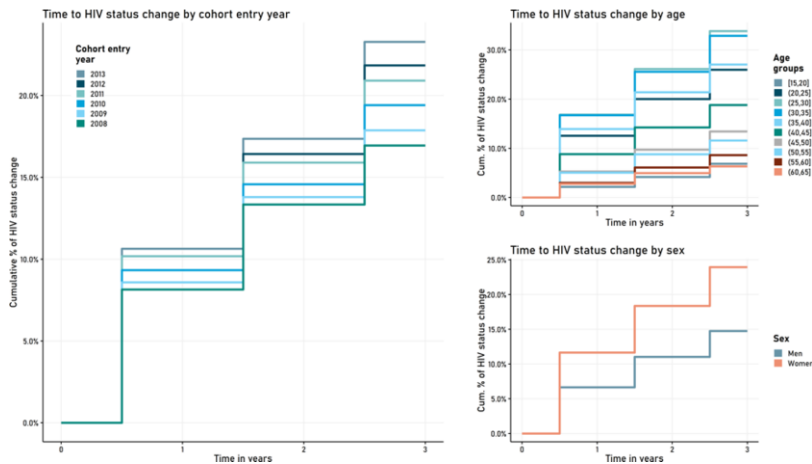

Figure 3. Unadjusted survival curves for time until HIV knowledge status change in the 3-year follow up sub-cohort of newly enrolled patients.

Figure 4. Hazard ratios from Cox proportional hazards model exploring the association between time until HIV knowledge status change, age, sex and cohort entry year in the 3-year follow up sub-cohort of newly enrolled patients.

4. Discussion

When applied to our population, the performance characteristics of the original algorithm were similar to those initially reported by the authors. EMRs combined with validated algorithms provide a useful source of information for monitoring temporal trends.

In our results, patients between 20 and 40 years of age, showed to be consistently more likely to have at least one HIV test and thus change their HIV knowledge status from 'unknown' to 'known'. This, combined with the overall upward trend of status change over the years that we found, is promising for the future given the clear benefits of early diagnosis that have been demonstrated over the last decade[1]. Nevertheless, the lower proportion of older adults that have had access to an HIV test in our study population is of concern given the higher comorbidity and mortality associated to older adults with delayed HIV diagnosis[2].

5. Conclusion

We were able to validate the algorithm developed by Felsen et al. in our population, which showed to have similar performance metrics as the ones reported the authors. When applied to our cohort, we found that HIV status knowledge change has been increasing, particularly since 2013 and that it seems to be independently associated with sex, age and cohort entry year.

Abstract. Global public health surveillance relies on reporting structures and transmission of trustworthy health reports. But in practice, these processes may not always be fast enough, or are hindered by procedural, technical, or political barriers. GPHIN, the Global Public Health Intelligence Network, was designed in the late 1990s to scour mainstream news for health events, as that travels faster and more freely. This paper outlines the next generation of GPHIN, which went live in 2017, and reports on design decisions underpinning its new functions and innovations.

Keywords. Public Health, Syndromic Surveillance, Natural Language Processing

1. Introduction

Global public health surveillance relies on reporting structures and transmission of trustworthy health reports. But in practice, these processes may not always be fast enough, or are hindered by procedural, technical, or political barriers. At the same time, the news travels much faster and more freely, certainly in this day and age. Recognizing that, Public Health Agency of Canada has been operating the Global Public Health Intelligence Network (GPHIN) since 1997, designed around capturing mainstream media stories from around the world, analyzing them, and then disseminating the insights globally, through WHO, for rapid responses such as initiating treatment and vaccination efforts, and slowing spread through travel advisories and port-of-entry screening.

This paper describes the efforts and results from the GPHIN rejuvenation project.¹ It provides an overview of the (added) functionalities, design decisions, and high-level implementation details. It also aims to inspire readers that are looking to extend these ideas to other types of real-time, broad scope surveillance efforts in life sciences.

2. Background

For a detailed overview of disease surveillance principles and systems, we refer to review papers on this topic. Abat et al. in their 2016 review paper [1] put multiple syndromic surveillance efforts in perspective, citing multiple data sources from the environment (including weather and animal data), population behaviours (including drug sales and

¹ GPHIN renewal was a team effort. The authors wish to acknowledge the contributions of research, development, operational, and support staff at National Research Council and Public Health Agency of Canada.

inter- net use), health care (clinics and hospitals), and demographics. We note that mainstream media was not considered in this review. Barboza et al. [2] analyzed several earlier bio- surveillance systems and concluded that they are indeed generally effective at publishing information about infectious diseases using news media compared to a goldstandard.

In addition to human disease surveillance, there are monitoring systems for livestock health that can inspire us. Lower privacy concerns surrounding animals have contributed to quicker advancements of such systems. Additionally, problems with livestock health can lead to human health concerns downstream, as animals can function as human disease vectors, and livestock epidemics can affect the human food supply chain [9]. EpidVis [7] is one such initiative that combines news collection with compelling visualizations for animal epidemiology.

GeoSentinel is a syndromic surveillance network that collects and disseminates reports on sicknesses in travellers. The information can inform pre-travel preparation, as well as guide post-travel differential diagnosis when a recent traveller has fallen ill [8].

The first version of GPHIN was conceived in the late 1990s, and soon proved its worth by enabling early detection of the 2003 SARS outbreak [6]. While the premise of the system remained relevant, advancements in software technology and data processing methods warranted a ground-up rejuvenation effort, which this paper reports on.

3. Methods and Results

The base architecture of GPHIN involves data intake, data processing, information storage, and interactive user tools [3]. In many cases, third-party or off-the-shelf components are used. Data originates from multiple sources, the majority of articles arriving through a large media aggregation service, others through curated RSS feeds – news sites, public health organizations, product recalls, and some high-relevance epidemiological (micro)blogs. Processed and tagged data are then stored in a relational database and also in an off-the-shelf full-text search tool, for analysts to search, retrieve, and digest.

A number of innovations were implemented. We highlight several of these in the following paragraphs, starting with its multilingual capabilities, including translation.

Multiple languages: GPHIN is a global effort, and as it uses local-level mainstream media signals, it must be able to process multiple languages. GPHIN processes data in ten languages: English, French, Spanish, Portuguese, Russian, Arabic, Farsi, Simplified and Traditional Chinese, and Indonesian – covering logograph, abjad and alphabet scripts and covering both left-to-right and right-to-left languages. Text analytics takes place partly in the language of origin (keyphrase extraction from restricted phrase lists), partly based on English machine-translations of the source document. Pragmatically, the Microsoft Azure Translate API was selected to detect the language of source material and translate it to English. These translations are somewhat noisy, and are never used as full substitutes to the source text, but even lossy translation can inform human analysts as well as various machine analytics components such as classifiers. Occasionally, downstream problems such as ambiguity can be averted by using modern context-sensitive machine translation algorithms: for example, the Chinese character can mean *twenty-first*, the family name *Ma*, or *horse*, and only one meaning is relevant when tracking equine diseases.

Relevance scoring is a function that discriminates first-line reports from background stories, retrospectives, opinions, policy documents, or any story that was accidentally caught by the aggregator service (e.g., “Bieber fever”). The technique is implemented as a binary classifier but with a confidence estimate that allows for ranking and flexible threshold setting. The classifier [5] is built around a machine learning classifier (SVM) using a set of approximately 1400 documents represented as unrestricted word and character n-grams. Articles with a high relevance score are published immediately, while low-scoring articles are automatically suppressed; only the remaining medium-relevance articles are triaged by analysts.

Information extraction: Medical terms in text are detected and mapped to UMLS by MetaMap Lite. The tool is restricted to a set of semantic types that is generally relevant to the public health community – largely syndromes and disease vectors. Subsequently, a hand-curated blacklist of common false positive terms is applied. The resulting annotations inform downstream components such as clinical reasoning, and links to UMLS definitions and ontology elements are provided next to articles. General named entities, such as person and organization names, are tagged using Stanford CoreNLP’s named entity recognizer. Heuristics were created to infer people’s job titles when mentioned, as well as to consolidate organizations’ full names and acronyms.

Geographic entity resolution: One part of situational awareness is knowing precisely where things are happening. We use Stanford CoreNLP’s named entity recognition plus heuristics to resolve mentions of geographic entities (countries, states/provinces, cities/towns, some lakes, some regions) to latitude-longitude coordinates and to canonical forms in the Geonames ontology so that they can be counted and mapped, collecting synonymous mentions of places and inferring parent-child relationships. When large outlets report on Tokyo or New York, local news sites may specify the sub-city (Yokohama or Shinjuku; Queens or Tribeca). A search in GPHIN for Tokyo will include all sub-cities, which makes it easier to synthesize very local media from a global perspective. This function also reconciles synonyms and language differences, coalescing multiple spellings/forms into a single known entity. Non-unique place names (e.g. London, UK versus London, Ontario, Canada) are resolved through heuristics that take into account where an article was published. Geo-tagging allows users to quickly drill into details about the geography of a document, checking population sizes, median age, poverty rates, and human development index measurements, for example.

Deduplication: Near-duplicate reports on the same incident are unavoidable when many media outlets republish newswire articles verbatim. To avoid duplicate stories hijacking trend detection algorithms, a duplicate detection algorithm was devised. The technique is built on two main principles: text edit distance, where a certain percentage of the word triplets in the article must be the same; and shingling, an observation that if all possible three- or four-word phrases are randomly assigned a number, sorting and sampling the set of such unique numbers for the phrases in two documents produces a substantially similar sample for documents that are similar but not necessarily identical. This solves the challenges like editors lightly rewording newswire articles for space constraints and adding/removing extra paragraphs of context at the end of an article. Duplicates are not removed but clustered / flagged as such, and the initial version among candidate duplicates is used as the exemplar. Minor but critical differences, such as an updated death count, are extracted using StructPred and tracked separately.

Narrative discovery and change point detection: On a daily basis, it looks for statistically unusual pairs of non-generic ontology keywords plus locations, and publishes these in a list of new “narratives”. As new articles come in to the system that

match each such pair of keyword plus location, it aggregates the content and tracks the narrative. While GPHIN may ingest as many as 10 000 new articles in a given day, the number of new narratives tends to be between 20 to 50 daily, which is small enough for an analyst to digest. For narratives that span at least several days, GPHIN applies topic modelling technology [10] to estimate when the language of the narrative is changing – when the language of an infectious disease pandemic is changing from uncertain to certain, or from investigation to response to rehabilitation, and so on. While GPHIN was designed around data streams that carry more noise than permissible for highly sensitive aberration detection algorithms, this combination of narrative discovery plus change point detection accomplishes a similar goal of trend detection and tracking.

User interface: The dynamic and faceted nature of the task is supported by a range of user interface modes. Figure 1 illustrates some of these. The basic interaction model in GPHIN is a set of filtering criteria coordinated with a colour-coded map, a configurable bar graph (showing activity over time or top keywords/locations/categories), and a list of documents. If a user has a hypothesis to test, a user might compose a search for a tagged syndrome in a geographic area, and then drill down by clicking on red hot spots on the interactive map or drill down into increasingly specific keywords or combinations thereof (Figure 1, left). If the event is a serious outbreak or a mass gathering, there are integrated report generation tools to support daily surveillance workflows outside the tool – users can tag and collate documents into topical reports, and GPHIN analysts can highlight portions of text within documents. Analysts can disseminate their findings via e-mail and RSS, while recipients can specify their own alert filters.

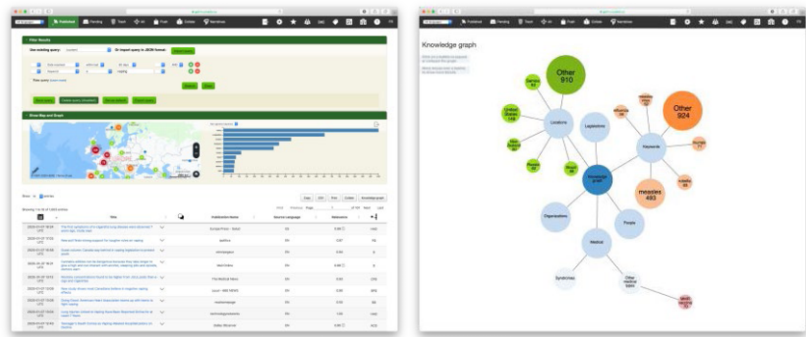

Figure 1. Coordinated search, map, and graph tool (left); knowledge graph for a measles outbreak (right)

GPHIN also supports workflows where the user has no specific hypothesis. The recently discovered narratives are listed with recent activity time series graphs, extractive summaries [11], and any detected inflection points. A further tool that GPHIN provides to try to illustrate surprising correlations is a basic knowledge graph (Figure 1, right), placing top keywords, locations, people and medical entities in bubbles. Location bubbles are linked when they are geographically adjacent. GPHIN is used primarily for monitoring current events in recent news, but also supports retrospective research, whether for psychoactive substances [12] or for analysing how media reporting changed the behaviour of the general public in the midst of past pandemics [4].

4. Discussion

GPHIN currently has more than one thousand registered user accounts in 56 countries, representing public health, governments at various levels, military, research, education, diplomatic, and travel organizations, from global to municipal. Aside from day-to-day syndromic surveillance activities, GPHIN was used for specific mass gatherings and summits (Olympics, G7), as these tend to come with exceptional volumes and directions of human (and therefore disease) travel. Surrounding the 2016 summer Olympic Games in Rio de Janeiro, WHO epidemiologists were not just concerned about Zika, but also that an ongoing MERS outbreak in the Middle East might migrate to Rio.

As domain knowledge was kept separate from the software code, we have since expanded the platform to support food safety surveillance (food, animal, and plant hazards, for example) and natural disasters in the context of public safety.

5. Conclusion

We presented an overview of added functionality to a global syndromic surveillance tool that leverages local mainstream media articles, in a range of different languages, to provide a rapid and global view to public health officials.

Abstract. Online digital tools are considered an innovative method to promote HIV, hepatitis and STIs prevention, testing and treatment services, overcoming individual and social barriers, especially for younger people and other, possibly hard-to-reach, target population groups. In this paper, we introduce INTEGRATE RiskRadar, a web and mobile application developed in the scope of the EU-supported INTEGRATE Joint Action (JA), that aims to enhance the integration of combination prevention, testing and linkage to care for HIV, hepatitis, STIs and tuberculosis by providing integrated information and digital tools regarding all four diseases to population groups at increased risk, aiming to eliminate the individual and social barriers to effective adoption of prevention practices, testing and linkage to care, and thus reduce the incidence and burden of these diseases in the European Region.

Keywords. Human immunodeficiency viruses (HIV), hepatitis, sexually transmitted infections (STIs), tuberculosis (TB), integrated approach, prevention, combination prevention, testing, linkage to care, eHealth, mHealth.

1. Introduction

Despite the fact that the global HIV response has resulted in impressive achievements, HIV epidemics continue to have a profound impact on the health and lives of millions of people worldwide [1]. At present, the coverage of the HIV services is still inadequate, and the rate of their expansion has to be accelerated to meet the 2020 target as well as the 2030 sustainable development goals (SDGs). Equally important, one of the key challenges is the burden of HIV coinfections, namely sexually transmitted infections (STIs), viral hepatitis and tuberculosis (TB), and the impact they have on HIV prevention, treatment and the related increasing morbidity and mortality [1]. This calls for the implementation of several prevention strategies that, if combined, may have additive and synergistic effects on reducing new HIV transmission incidences. Combination prevention is the strategic and coordinated use of biomedical, behavioural and social/structural activities operating on various levels (individual, community, societal) to reinforce the sustained impact of HIV prevention. The World Health Organization

¹ Corresponding Author: Christine Kakalou, Institute of Applied Biosciences, Centre for Research and Technology, Thessaloniki, Greece; E-mail: ckakalou@certh.gr.

(WHO) emphasises that the existing momentum of the HIV response should be bolstered by new evidence- and rights-based combination prevention tools that are tailored to the needs of specific people and communities, especially those of vulnerable population groups that are disproportionately affected by HIV [1].

In this context, digital tools are considered an innovative method to promote HIV, hepatitis and STIs prevention, testing and treatment and overcome individual and social barriers, especially for young people and hard-to-reach target population groups [2], given the rapid uptake and ubiquity of smartphones and Internet access in Europe. Although notable progress has been achieved recently in the fields of eHealth and mHealth, the main focus has been on the management of non-communicable diseases (NCDs), rather than infectious ones. While a growing pool of HIV/hepatitis/STIs-related apps and online tools exists [3], they mostly target medication adherence and specific groups [4]. Several gaps remain in the implementation agenda, e.g. the inclusion of more key populations and other points along the care continuum besides treatment [4] [5].

In this paper we introduce INTEGRATE RiskRadar, a web-based and mobile application developed in the scope of the INTEGRATE joint action (JA), that aims to enhance the effectiveness of combination prevention for HIV, hepatitis, STIs and TB. By providing integrated information and digital tools regarding all four diseases to the public regardless of gender, age, sexual orientation or insurance status, we aim to eliminate the individual and social barriers to effective adoption of prevention practices, testing and linkage to care, and to thus reduce the incidence and burden of these diseases in EU member states.

Figure 1. Overall *RiskRadar* development process and landing page for Web tool and mobile app.

2. Methodology

Our design and development approach focused on the assessment of available relevant digital tools to identify promising and innovative features and their consequent adaptation to address all four disease areas. The design of this new integrated ICT (information and communication technology) toolkit accommodates the distinctive needs of various vulnerable groups, i.e., *Young adults* and *men who have sex with men (MSM)* who adopt new partner-seeking and sexual behaviours [6], might engage in illicit drug use [7], report an enhanced need for privacy and anonymity, especially in some countries and demand an attractive and modern user interface (UI) [8]. For *persons who inject drugs (PWID)* risk reduction advice is needed, while *migrants* require a toolkit

with mobility and ubiquity to help them acquire an understanding of additional risk factors. Finally, *prisoners and homeless persons* would benefit from an easily accessible, fast and simple web interface available at clinics and NGO sites, focusing on risk reduction. The RiskRadar development methodology involved three phases (**Figure 1**).

2.1. Mapping Exercise

First, a mapping exercise was conducted, aiming to identify existing ICT resources addressing combination prevention strategies worldwide with additional focus on tools implemented on a national level in the European region. A "mapping matrix" was introduced to align the data collection process, where a specific structure was proposed, featuring fields describing the tool, the target audience, the disease(s) addressed and its availability. INTEGRATE partners were invited to contribute to this phase by submitting any relevant tool they were aware of. The outcomes of the review were harmonised, resulting in the complete mapping matrix of ICT tools, consisting of 115 candidates.

2.2. Evaluation of Existing Tools

To evaluate the collected tools, we determined the appropriate criteria by analysing the matrix and excluding any non-ICT tools such as online guides, manuals or training modules. These were flagged for further consideration during the JA's capacity building activities. The final list of tools for consideration was reduced to 53 and divided into two groups, according to their respective uses in the care continuum, i.e., **Group A-Prevention**, containing 29 tools related to prevention, harm reduction and PrEP (pre-exposure prophylaxis); and **Group B-Testing**, containing 24 tools related to testing, partner notification and linkage to care. A two-fold, more thorough review of these tools followed based on the following criteria: (a) perceived relevance and adaptability to the JA purposes, and (b) adaptability, reproducibility, and data relevance from a technical standpoint, since the vast majority of the tools addressed a single disease.

The review process identified seven tools that scored high in all criteria, then the results were discussed with respect to their strengths, weaknesses and shortcomings with the JA steering committee members. An initial proposal for the RiskRadar structure was formulated according to the toolkit's intended use, target audiences, and overall scope.

2.3. RiskRadar Components

The proposed toolkit features modular components that could be enabled according to the capacity and intended target audience. The following components were defined: (a) a **Factsheets** component offering basic information regarding the different diseases; (b) a **Risk Calculator** (RC) tool that allows users to assess if they have been exposed to the diseases based on underlying risk assessment algorithms, tailored to each key group's needs; (c) a **PrEP** component to inform the user of this novel prevention tool; (d) a **Test Finder** featuring filtering capabilities per disease, type of point-of-care, and country; (e) a **Reminders** component to help users stay on track with their respective testing schedule; (f) a **Partner Notification** (PN) tool based on the combination of existing services, and (g) a **TB** component offering information and highlighting the differences with the other three disease areas in terms of transmission, prevention, and care. RiskRadar will be piloted in Croatia, Italy and Lithuania; thus appropriate translations of its components have been prepared to accommodate language barriers.

Risk Calculator

Are you vaccinated for hepatitis B?

Yes No I don't know

← Risk Calculator

Integrate

Why are you using this risk calculator?

☐ I am HIV+

☐ My partner is HIV+

☐ Both me and my partner are HIV+

☐ I had condomless sex with someone

☐ I inject drugs

☒ I'm just curious

CONTINUE

Result:

Condoms when used always and correctly are very effective at preventing HIV and reducing a risk of STI. Take the Condom Test to help you choose the right condom for you. Other sexual acts such as fisting and sharing sex toys without cleaning them afterwards can also expose you to hepatitis and STIs. It is recommended to get tested at least twice per year or more often if you have sex often and with different partners.

You might have been exposed to HIV and hepatitis through shared injecting equipment; you should get tested. Remember that injecting or using drugs exposes your health to other risks and harms. If you would like to stop using drugs but cannot make it on your own, it is important that you seek help. You can also seek advice and learn about harm reduction strategies, in order to reduce as much as possible the risks associated to drug use.

It is recommended that all gay and bisexual men get vaccinated for Hepatitis A & B; consider asking your medical doctor for a Hepatitis A & B vaccination (You will need a test before getting vaccinated).

Screening for hepatitis C is recommended if you come from Central Asia; Asia; Sub-Saharan Africa; Middle-East; Central and South America where the virus is highly prevalent.

Tuberculosis is highly prevalent in Eastern Europe, Sub-Saharan Africa or Asia – so if you originate from these regions it is recommended to consult a medical doctor for TB screening.

Got it! Retake quiz Take the condom test

Figure 2. (a) Question of the RC component in the web app (upper left part) and question from the RC component in the mobile app (lower left part); (b) the result of the RC (the right part).

2.4. Design and Development Considerations

The main challenge concerned the RC component, since (to the authors' knowledge) a comprehensive tool for calculating the inextricable nature of the combined risks for all four disease areas tailored to the high-risk key populations consisting RiskRadar's end users is missing. A consolidation of all available guidelines by WHO and ECDC reinforced the algorithms derived by the previous analysis of the partial risk assessment tools for each disease. The RC decision tree resulted from an extensive iterative process of obtaining input from all partners, while its final release was approved for official translation in the piloting countries' languages. As regards the information components, contacts with central information sources were established, such as NAM for the Test Finder, "PrEP in Europe" for the PrEP component and ECDC for the factsheets.

Overall, the design approach relied on (a) *effective communication strategies* outlined by WHO and ECDC, and (b) *informed UI design* based on the literature findings of relevant websites and mobile apps [9]. Emphasis was placed on offering adequate information to the user to make informed decisions and possibly adjust risky behaviours while keeping users with low health/eHealth literacy engaged with the app.

3. Results

RiskRadar is available as a web application and as native Android and iOS mobile apps, integrating the various components presented in section 2.3. Overall, our development approach was based on the following pillars: (a) *easy to update content* and (b) *adaptable content to fit diverse target groups*, via a modular design for the RC answers which can be independently modified according to the target audience (Figure 2); (c) *easy to use, intuitive and interactive UI*; (d) *use of acceptable, non-judgmental, non-threatening and non-fear-inducing language and imagery*, through an iterative process of consulting with various public health institutions and relevant NGOs; (e) *patient empowerment* by providing direct PN services as well as a self-evaluation risk calculator tool, and (f) *ensure that the user feels safe and also that their trust, privacy, and confidentiality are clearly perceived while using the app*. The latter is achieved by establishing privacy and cookie policies that explicitly state the anonymisation and encryption mechanisms

employed, featuring them prominently in the application; namely the use of anonymous, unique random codes to access the PN component, the encryption and enhanced security during data transfer and the absence of any identifiable information in the RC component.

Each pilot country targeted different populations. Currently, the pilot sites are testing RiskRadar before its release to the public. The outcomes of the pilots will be used to evaluate RiskRadar's effectiveness and usability. A short questionnaire was added to support pilot exercise, given that it is difficult to evaluate the effectiveness of ICT tools' in the prevention of the four diseases. This is because measures such as the number of web accesses or downloads do not give a precise measure of the usefulness of ICT tools. Nonetheless, RiskRadar has the potential to be an appealing source of information for the prevention and testing of these diseases. Especially for people who encounter barriers to care, RiskRadar could facilitate entry to and retention in the healthcare system.

4. Conclusion

In this paper, we presented the overall approach regarding the design and development of an integrated toolkit accessible over the web or a dedicated mobile application, in line with the current public health authorities' guidelines. The development of RiskRadar exploits the expertise and various insights from INTEGRATE's inter-disciplinary consortium, thus enabling the synergy of biomedical and behavioural prevention and offers a new level of privacy, confidentiality and security as well as the opportunity to satisfy the diverse needs of various target groups at the same time (scalability).

Abstract. Administrative claim data is believed as one of the promising data set to augment the mandatory surveillance system which suffered from under-reporting and delay in reporting. Therefore, this study aims to examine whether the Indonesian National Health Insurance (INHI) sample data could complement dengue case-based surveillance system in a more practical way. Afterwards, this analysis also identified several future opportunities and challenges in improving the dengue surveillance system. We utilized the referral care table linked with capitation and non-capitation-based primary care service table from 2015-2016. Data cleaning, query and visualization were performed using Tableau Public and Microsoft Power BI. Result shows that dengue referral pattern is indicating the opportunity to detect dengue cases in an earlier stage and high utilization of referral care disclose the patient behaviour. Therefore, anonymous INHI sample data set potentially to complement dengue traditional surveillance system. A huge number of health facilities as data providers, bridging and interoperability chance and opportunity of early detection are identified as future opportunities. However, we also determine challenges involving how to provide the mechanism for the quick and interoperable reporting system, how to construct supportive regulation and anticipatory approach regarding the change in dengue diagnosis criteria as the implementation of ICD 11 code. Thus, practical approaches should be prepared to support the utilization of INHI sample data.

Keywords. Dengue, public health surveillance, claim data, Indonesia

1. Introduction

Dengue was identified as the most rapidly spreading vector-borne disease including in Indonesia with national incidence rate count for 24.73 per 100,000 population [1, 2]. And even has been circulated over 50 years, dengue viruses remain to persist in 440 districts or 85.60% of total area and resulting in an immense burden [2]. Therefore, an adequate dengue surveillance system might be a key to tackle the dengue occurrence.

¹ Corresponding Author, Graduate Institute of Biomedical Informatics, Taipei Medical University 15F., No. 172-1, Sec. 2, Keelung Rd., Daan Dist., Taipei, Taiwan, Email: emilysu@tmu.edu.tw.

But unfortunately, most contributor countries for global dengue infections are suffering from poor reporting systems [1] that result in a huge under-reporting issue. Research from Bandung, Indonesia, reveals that the adequacy of case reporting was only 45.7% [3]. Another problem that encounters with dengue surveillance system in Indonesia is the delay in reporting that takes days to month even though dengue cases should be reported within 24 hours after confirmed diagnosis [3, 4]. However, adequacy and timeliness are important aspects in order to provide a near-real-time response within the dengue incubation period.

Under-reporting and delay in reporting might come because of the absence of the integrated reporting system. Dengue reports from hospitals are reported to the district health offices with diverse formats through email, online messaging, or paper-based reporting system. Then, data from districts are submitted monthly to the province and national level with various structures of the report and in aggregate forms. This condition may cause dengue control, and prevention programs act too late. Thus, strengthening the dengue surveillance system requires a massive effort, including initiatives to identify potential data sources that sought the traditional surveillance system.

Given the widespread implementation of Universal Health Coverage (UHC), many studies reveal the novel uses of health claim data to augment the mandatory reporting system and provide disease-specific information [5-9]. This approach is potential to be examined in Indonesia since UHC has been implemented in 2014, along with the implementation of online claim reporting system which covers 221.203.615 members and 27.315 health facilities including the private sectors [10, 11].

Recently, as part of the open data implementation, the Indonesian Health Insurance Agency (IHIA) launched the sample data that record transactional data either in primary or secondary health care [12]. These data sets derived from 1.7 million members that explained in four relational tables, including membership, capitation, non-capitation-based primary health care and referral care table [13]. And even only derived from 1% of the total membership in 2015 using stratified random sampling [12], this data set contains a relatively short range of data records [14]; still, this data set could be the only nationally representative administration data set that is currently available and potentially updated yearly.

Accordingly, this study aims to examine whether INHI sample data could complement dengue case-based surveillance system in a more practical way. Previous studies defined the usefulness of health claim data using similarity standards with routine surveillance systems [5-7]. Nevertheless, assessing whether health insurance claim data could provide disease-specific information could be more useful for decision making. Hence, this study evaluated the utilization of INHI sample data through assessment of dengue specific information related to referral patterns. Afterwards, this analysis also identified several future opportunities and challenges in improving the dengue surveillance system using INHI sample data.

2. Method

This study uses anonymous INHI sample data (2015-2016). In order to provide dengue specific information related to referral patterns, we utilized the referral care table linked with capitation and non-capitation-based primary care service table. Dengue cases included in this analysis were in-patient cases, A91 ICD-10 code and primary visit. The patient IDs of dengue cases then were traced in capitation and non-capitation-based

primary care service table within seven days before patients were hospitalized. Severity level and health outcome then retrieved from referral care table. Data cleaning, query and visualization were performed using Tableau Public and Microsoft Power BI to illustrate dengue referral patterns. And as a future depiction, we also identified opportunities and challenges regarding the utilization of INHI sample data by comparing it with current policies on dengue surveillance system applied in Indonesia.

3. Results

Five thousand eight hundred ninety-one (5,891) dengue cases from the referral care table were obtained during 2015-2016. Within seven days, 1,131 cases (19%) were recorded in primary health care both in capitation and non-capitation-based primary care service. 13% of those cases then were registered in referral care (outpatient) along with 6% of dengue cases that treated immediately in outpatient care. But, most dengue cases (75%) were identified as having no interaction with the gatekeeper before hospitalized.

Figure 1. Referral patterns of dengue cases (2015-2016)

Furthermore, the Sankey diagram illustrated the dengue referral pattern, as shown in Figure 1. This graph showed dengue treatment stream linked with severity level and health outcome. Sankey diagram showed that most of the dengue cases were identified as having no interaction with the gatekeeper before hospitalized even 82% of cases were classified as level 1 severity.

Hereinafter, future opportunities and challenges regarding the utilization of INHI sample data are identified and listed in Table.1

Table 1. Future opportunities and challenges regarding the utilization of INHI sample data

Num	Opportunities	Challenges
1.	An increasing number of hospitals are potentially providing dengue data as their contribution to the UHC system	How to develop a mechanism for the quick and interoperable reporting system
2.	19% of dengue cases have been detected in primary health care, promising the early detection before hospitalization	How to construct regulation involving primary health care into the dengue surveillance system
3.	IHIA has providing bridging facility between the IHIA reporting system (PCare and INA CBGs) and health centre information system (Simpus) or hospital information system. Therefore, dengue cases recorded in gatekeeper and referral care can	How to anticipate change in dengue diagnosis criteria as the implementation of ICD 11 code

be easily managed cross-platform for surveillance purposes

4. Discussion

Based on the Sankey diagram provided as a result, this study successfully demonstrated that anonymous INHI sample data could provide disease-specific information related to dengue referral patterns. Thus, INHI sample data potentially complemented dengue case-based surveillance systems in a more practical way. Provided information could be used for decision making.

Observed dengue referral patterns indicate two important findings. The first one is the opportunity to detect dengue cases earlier before hospitalization as 19% of dengue cases have been detected in primary health care. This chance is supported by the bridging facility between IHIA reporting system (Primary care or PCare) and public health centre information system (Simpus). Therefore, dengue cases recorded in primary health care can easily manage cross-platform for surveillance purposes. However, the challenge is how to construct regulation that counts primary health care into the dengue reporting system.

Current regulation [15] involves gatekeeper in the system, required them to send weekly and monthly dengue cases to district health offices. But decision makings related to dengue control and prevention are taken using dengue reports provided by referral health care facilities. In fact, involving gatekeeper into the dengue surveillance system is not a big through. Since previous regulation has initiated an integrated dengue surveillance system that put gatekeeper and referral care as the same level data source [16]. Thus, strengthening policies are needed.

Another significant finding is the massive utilization of referral care discloses the patients' behaviours that tend to access the hospital. It may be caused by the rise of literacy level [17] as the knowledge of dengue symptoms, and risk perception play an important reason for visiting a doctor [18]. However, it might also an opportunity since dengue cases recorded in the IHIA reporting system (Indonesia case-based groups or INA CBGs) in hospitals also could be linked with the hospital information systems. Hence, dengue cases could be directly imported to the dengue surveillance system through data linkage. This approach would potentially shorten the dengue tiered reporting system. And as the increasing number of hospitals that contribute to the UHC system, it might be a good opportunity since UHC in Indonesia target the national coverage in 2023. Consequently, developing a mechanism for quick and interoperable reporting systems is required.

Successful implementation of a simple dengue reporting system has been recorded in Taiwan [19], which might be a good example. Minimal reporting steps lead to high adherence (99%) to report cases within 24 hours. Thus, dengue surveillance system utilizing claim data should be designed simply and facilitated with interoperability features between PCare, INA CBGs, Simpus, hospital information system, local, provincial and national health offices.

The latter action is also necessary to help anticipate change in dengue diagnosis criteria. Although ICD 11 code was released on June 2018, the INHI sample data still makes use of the former ICD 10 code. In the new ICD 11 code, dengue is divided into

four different diagnoses [20] which is completely different from the previous classification.

In conclusion, INHI sample data could provide disease-specific information related to dengue referral patterns. Therefore, this sample data set potential to complement the dengue traditional surveillance system. A huge number of health facilities as data providers, bridging and interoperability chance and opportunity of early detection are identified as future opportunities. However, we also determine several challenges involving how to provide the mechanism for the quick and interoperable reporting system, how to construct supportive regulation and anticipatory approach regarding change in dengue diagnosis criteria as the implementation of ICD 11 code. Thus, practical approaches should be prepared to support the utilization of INHI sample data.

Intelligent Tools for Precision Public Health

Anya OKHMATOVSKAIA^{a,1} and David L. BUCKERIDGE^b
^aMcGill University

Abstract. The idea of “precision public health” (PPH) was proposed as an alternative to a one-size-fits-all approach to improving population health, which is not always effective. PPH aims to develop and apply interventions in a customized way, taking into account the detailed information about the target group. To enable the implementation of PPH in practice, we are developing an ontology-driven software platform that provides: a) access to detailed up-to-date information about population health, b) a structured machine-readable repository of evidence about public health interventions, and c) a set of intelligent tools to facilitate the assessment of evidence transferability, i.e. to determine how well certain interventions fit a given population.

Keywords. Evidence-informed decision-making, ontology

1. Introduction

Public health organizations tend to develop general policies and programs using a one-size-fits-all approach to improving the health of populations, which is not always effective in achieving the desired outcomes. Recently, the idea of “precision public health” (PPH) was proposed, where a variety of traits of subpopulations or even communities are detected and tracked to enable the development and targeted application of interventions that are best suited to that group [1]. This concept of ‘precision’ is borrowed from the more familiar context of ‘precision medicine’, which refers to targeting therapy (particularly for cancer) using detailed data about individual genomic and other traits on one hand, and available evidence on the effectiveness of treatment options in different patients under different conditions, on the other hand. At a population scale, PPH similarly aims to use the detailed information about a defined population and evidence about the effectiveness of available interventions in different populations under different conditions, to precisely match an intervention to a population for best results.

Despite the general appeal of this vision, the computational tools to support the implementation of PPH in practice are still lacking. Most PPH frameworks agree on prioritizing the development efforts in the three areas: 1) access to detailed population health information, 2) access to evidence on health interventions, and 3) tools for combining population information and evidence. Artificial intelligence methods, including semantic technologies, have the potential to address the challenges in all three priority areas of PPH. Using software ontologies to organize both population health information and intervention evidence can facilitate access to these resources and support the development of intelligent decision-support tools. In the rest of the paper, we first introduce our initial work in enhancing access to population health information through the Population Health Record (PopHR) project, we then describe the Interventions Knowledgebase, which extends PopHR to provide access to evidence about public health

¹ Anya Okhmatovskaia, Corresponding author, E-mail: anna.okhmatovskaia@mcgill.ca.

interventions, and finally, we discuss future work towards the development of intelligent tools for transferability assessment.

2. Population Health Record

Just like personalizing therapy in precision medicine, developing targeted public health interventions requires the capacity to integrate, analyze, and interpret a growing volume of heterogeneous population health data. Decision-makers must have access to timely and accurate indicators of population health, including health information about diseases and risk factors and information about available resources. Regrettably, state-of-the-art health information systems tend to suffer from certain weaknesses in their design and operation, including out-of-date static indicators, insufficient spatio-temporal resolution, and limited transparency of computational algorithms and data sources. As a result, they do not provide sufficient precision in describing populations that could be targets for interventions. The PopHR is an ontology-driven web-based software platform that was designed to address the shortcomings of the existing systems and provides access to comprehensive, timely and detailed information about population health [2].

In order to collect, align, integrate, and transform data from multiple sources, the PopHR relies on a suite of ontologies that encode an explicit semantic framework for population health. This framework includes taxonomies of population characteristics, diseases, determinants of health, a multi-axial classification of health indicators, spatio-temporal relations, etc. In addition, it incorporates epidemiological causal knowledge, identifying upstream and downstream relationships for different health conditions. The PopHR uses this framework to organize and present health indicators in a meaningful way. The current version of the PopHR focuses on chronic diseases and their risk factors. With partners from the Institut National de Santé Publique du Québec (INSPQ) and funding from the Public Health Agency of Canada (PHAC), we are in the process of deploying the PopHR in the province of Quebec for routine use by public health professionals.

By providing access to the detailed population health information, PopHR supports one of the PPH priority areas, and serves as a foundation for the development of intelligent tools in the other two areas. Extending the PopHR to support integrated access to evidence about interventions and decision-support tools that would suggest to the user the interventions that are likely to be the most effective in a given population (something that requires juxtaposition of evidence about an intervention with information about a population in a target region) is the focus of our current research. As far as we know, no existing system currently supports such functionality.

3. Interventions knowledgebase

Biomedical literature has accumulated an enormous amount of evidence documenting the effectiveness of health interventions in many populations and settings. This evidence, however, is neither readily accessible, nor encoded consistently, and therefore not easy to use for the purpose of PPH. The field of knowledge translation (KT) has made considerable progress to address this problem [3], including the development of searchable online repositories of evidence [4]. To date, however, these repositories rely heavily on manual curation, with the associated high costs of building and maintaining them. Keeping

up with the exponentially growing body of biomedical evidence comes at a cost of reduced precision of these repositories: most of them limit their focus to systematic reviews and exclude the original studies, and annotate the evidence coarsely with only a small set of intervention and study design characteristics, insufficient for precise matching of the evidence to target populations.

To enable the encoding of evidence with a precision sufficient for assessing its transferability to a defined population in the context of PPH, one needs a sufficiently expressive vocabulary. While all existing web repositories for health evidence use some sort of an underlying conceptual model to describe interventions and their effects, the model is often shallow and informal, which limits precision and presents a barrier for the use of automated tools to process such evidence. In contrast, a formal intervention evidence framework in the form of an ontology will provide the necessary level of expressivity, enable logical reasoning over existing evidence, and provide a foundation for automated retrieval and annotation of new evidence.

The most popular standard framework for describing health evidence, PICO, has been formalized as an ontology by the Cochrane group [5] and it identifies the essential components of evidence (population, intervention, comparison, outcome) and the relationships among them. The high-level PICO framework can be supplemented by more detailed vocabularies to further classify instances within each component. However, while extensive terminologies exist to systematize clinical interventions, and behavior change techniques, little work has been done to develop a standard vocabulary for describing public health interventions. To address this gap, we have developed an Ontology of Public Health Interventions (OPHI), which can be used to formally encode evidence about intervention effectiveness in a standard, machine-readable format.

3.1. Ontology of Public Health Interventions (OPHI)

To ensure that our ontology reflects a consensus among public health professionals regarding intervention classes and properties, we conducted a scoping review of literature to identify existing conceptual frameworks and classifications of public health activities. The search extended over articles in public databases (PubMed, Scopus, Google Scholar and Cochrane Library) as well as the grey literature: documents from PHAC, INSPQ, Public Health Europe, WHO, and the National Public Health Partnership. Two independent researchers examined the titles and abstracts of nearly 1000 articles for relevance, leaving around 200 articles for full-text review, yielding a total of fourteen sources to be synthesized. These sources included several formal ontologies and classification systems, as well as informally described conceptual frameworks and diagrams.

We extracted concepts from each of the 14 proposed frameworks along with their definitions. Some of the sources did not formally define any concepts that were used. As a result, many of the concept definitions had to be inferred based on the provided examples of usage and lists of child concepts or property values. We also identified a number of concepts that were used synonymously across different frameworks, as well as ambiguous terms that had different meanings in different frameworks. After the required disambiguation and merging of synonymous terms, we developed a synthetic conceptual model and formalized it using Web Ontology Language (OWL).

The resulting Ontology of Public Health Interventions (OPHI) builds on the basic structure introduced by the PICO ontology to capture health evidence, augments it with

the concepts and relationships from the synthesized frameworks, and provides a multiaxial classification of interventions based on settings, recipients, purpose and methods. As part of the PopHR ontology suite, OPHI is directly linked to other ontologies we developed previously for this platform, notably, the ontology of public health (PHOnt), which encodes a broader range of concepts relevant to public health practice (e.g. public health resources), and includes causal knowledge about health conditions and health determinants. This linkage is essential when it comes to assessing the applicability and feasibility of implementing interventions in new contexts and predicting their effects in target populations. Although OPHI specifically focuses on public health interventions, the underlying knowledge model is compatible with and suitable for encoding clinical interventions as well. This is important since evidence from clinical trials is more abundant compared to studies evaluating the effects of public health programs.

3.2. Sample knowledgebase of influenza interventions

To demonstrate how OPHI can be used within the PopHR infrastructure to support PPH practice, and to verify its suitability for annotating studies of interventions, we have created a small sample knowledgebase of interventions, focusing on influenza control². As much of the evidence related to influenza control focuses on vaccination, we have extended OPHI with a well-established Vaccine Ontology [6] to increase the annotation precision in this area. We selected four systematic reviews that focused on diverse aspects of influenza control measures (vaccine safety, effectiveness, vaccine uptake, non-vaccination prophylactic measures) and retrieved fifty-six associated studies. We manually extracted from this corpus the essential findings about the effectiveness of interventions and annotated all relevant terms and features of the interventions and study populations. We were able to align the relevant properties of study design, categories of interventions, characteristics of study population and types of outcome with the existing OPHI terms. Figure 1 presents a fragment of the encoding.

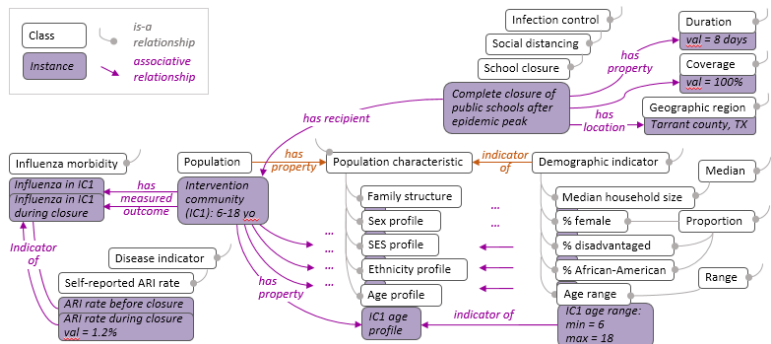

Figure 1. Sample encoding of influenza intervention evidence using OPHI (fragment)

In our pilot work building a sample knowledgebase of influenza control interventions, we demonstrated that OPHI provides a suitable semantic framework for describing and classifying existing evidence about public health interventions. While we believe that our ontology can be applied successfully to other subject areas, our experience encoding

² Subject area has been chosen because of the high burden associated with influenza, and because it has been extensively studied within clinical trials, and public health programs, and large amounts of evidence is available.

influenza vaccination studies reveal the potential need to incorporate additional vocabularies to achieve the necessary level of precision. Combined with the causal knowledge already captured in PopHR ontologies, the OPHI-based interventions knowledgebase would support searches for interventions with specific properties and with demonstrated effectiveness in specific populations and settings and will provide a foundation for the development of the intelligent tools for evidence transferability assessment. Another direction of our future work is exploring the potential of employing statistical natural language processing (NLP) techniques to automatically populate the knowledgebase with instances of interventions and evaluation findings from published literature and databases. Such automation has been previously demonstrated as feasible in the context of clinical trials [7]. The influenza interventions knowledgebase will provide a set of annotations that can be used for training the machine learning algorithms.

4. Future work

The third PPH priority area has seen the least amount of progress. In the context of PPH, to make an evidence-informed decision, one must have not only detailed information about target population and evidence of interventions' effectiveness but also the cognitive capacity to assess the 'fit' of the evidence to the target population. Systematic reviews, which constitute the standard of evidence for public health decision makers, estimate an intervention's impact over a range of settings and provide limited detail on the populations and conditions of included studies. This means that extensive additional information gathering from individual studies is usually needed to assess the potential effects in a local population setting. Given the complexity of this task, decision-support tools have the potential to facilitate this process significantly. To date, however, there has been little research on the development of tools and software to help practitioners effectively combine evidence about health interventions with population information.

The OPHI-based interventions knowledgebase will make characteristics of the study population used to generate evidence readily available for access by automated tools, while corresponding characteristics of the target population can be retrieved from PopHR data. With a set of conversion rules that account for various measures of the same characteristic, it will be possible to compare the two populations using measures of statistical and semantic similarity [8], and assess how well an intervention "fits" a given population and possibly estimate the expected effect of that intervention.

Abstract. Introduction: Prevalence of overweight and obesity are increasing in the last decades, and with them, diseases and health conditions such as diabetes, hypertension or cardiovascular diseases. However, hospital databases usually do not record such conditions in adults, neither anthropomorphic measures that facilitate their identification.

Methods: We implemented a machine learning method based on PU (Positive and Unlabelled) Learning to identify obese patients without a diagnose code of obesity in the health records.

Results: The algorithm presented a high sensitivity (98%) and predicted that around 18% of the patients without a diagnosis were obese. This result is consistent with the report of the WHO.

Keywords. Obesity, Overweight, Identification, Machine Learning, PU Learning

1. Introduction

Overweight and obesity epidemic prevalence has increased since the 1970s in most of the countries, affecting children and adults alike [1,2]. According to the World Health Organization (WHO) in Europe, more than 50% of the population is overweight, and 20% is obese (WHO Data and statistics, 2019). In Spain, obesity already affects 17.4% of the adult population, whereas considering obesity and overweight together, more than half (54.5%) of adults are overweight.

The most challenging feature of this situation is the increasing trend of people with obesity and overweight in our society. This trend is especially worrying due

¹Corresponding author. Email: viblasel@upv.es

to conditions and diseases that are associated with an excessive weight such as diabetes, hypertension or cardiovascular disease [3].

However, this increase in obesity and overweight among the population has not been reflected in hospital practice, which usually attends the problems derived from obesity but not the underlying condition [4]. For example, at the Hospital Universitario La Fe, in Valencia (Spain), the percentage of patients in the electronic health records with a diagnosis of obesity (278.00 and 278.01 ICD9 codes) is 2.4%. Also, the lack of anthropometric measures in the databases (only around 3%) makes it difficult to extract useful indicators for identification, such as the Body Mass Index (BMI).

Public policies and hospital interventions based on that data may lack correctness, producing biases in the conclusions extracted from it. Under this situation, other methods to know the real condition of patients are required. Among others to cross-reference with primary care data, active questionnaires to patients or data imputation are actions to mitigate this limitation.

To solve this identification issue, several restrictions should be considered 1) No specific information is compiled about obesity and overweight in the adult population; 2) Majority of samples are not labelled as obesity, overweight or no obesity, neither BMI is collected 3) real classes are unbalanced given the statistics about WHO.

With this scenario, we propose to develop a machine-learning model based on positive-unlabelled (PU) learning for obesity identification trained by positive and unlabelled electronic health records as a public health tool to estimate hidden positive patients with obesity before studying comorbidities at patient aggregation level. The authors developed this work in the context of the H2020 European project CrowdHealth (<https://crowdhealth.eu/>) to provide helpful tools for public policies' developers.

2. Materials and Methods

In this study, we analysed data from a total of 49805 anonymised patients represented by their basic demographics and information coming from the Electronic Health Records of HULAFE such as external specialist consultations, emergency room registries, hospital admissions, laboratory results and home hospitalization (UHD) registries. Ethical approval was obtained for this study from the Ethical Committee of Hospital Universitario La Fe (Ethical Code: 2016/0350).

We searched for conditions associated with obesity and overweight in the scientific literature [2,3,5] and created a list of concepts to query against the data, extracting a final set of predictive variables. These variables were mostly related to the frequency of diagnoses, frequency of visits to specialist and laboratory results about cholesterol. A total of 32 variables (see Table 1) composed the final version of the dataset. From the 49805 patients that formed our sample, 7033 (~ 14.12%) were labelled as positive for obesity, having an ICD9 code for obesity present, and 42772 (~ 85.88%) were unlabelled.

Table 1. Variables obtained from the dataset

Variables		
Stroke	Angiologists consults	Circulatory diags
Hypertension diags	LDL analyses	HDL analyses
Triglycerides analyses	Endocrine diags	Insuline Tests
Insuline-related emergencies	Cardiologist consults	Infarction diags
Cardiology diags	Coronary-related admission	Gastric issues
Gallbladder-related emergencies	Gallbladder-related admissions	Rheumatology consults
Musculoskeletal diags	Sleep issues	Sleep breathing problems
UHD onco	Radio or Quimio events	Oncologist visits
Protein analysis	Psiquiatric diags	Pain diags
LDL mean	HDL mean	Triglycerides mean
Diabetes diags	Age	

As mentioned before, the number of identified obesity patients in the Electronic Health Records (EHRs) are meagre. The authors hypothesise that among unlabelled patients there is a significant amount of obese patients ($\sim 17\%$ of the population) according to the statistics by the WHO. This problem belongs to the class imbalance type, which is characterised for having a majoritarian class where most of the samples belong [6].

Therefore a classic machine learning classification algorithm is not appropriate for this task. As a consequence, a correct approach under machine-learning discipline for dealing with our problem is PU Learning. Liu et al. in [7] define PU Learning as a semi-supervised technique for building a binary classifier based on positive and unlabelled examples. In PU Learning, two sets of samples are available for training: the P set of positive instances, and a U set, assumed to contain a mixture of both positive and negative examples but unlabeled at training time. This technique is particularly useful when the level of contamination, positive samples among negatives, in U is low (around 15%).

In concrete, we have used an implementation of the algorithm "Bagging Inductive PU Learning" (see algorithm 1) proposed by Mordelet et al. [8]. In this version, an ensemble of T classifiers is trained using the P set and a randoms sub-sampling of U set with size $|P|$ for each classifier. We implemented Mordelet's algorithm in Python 3 [9], using instances of the Random Forest (RF) [10] from the *scikit-learn* library [11] as classifiers in the ensemble.

To demonstrate the validity of PU Learning in the obesity identification problem we developed an experiment where we split the data randomly, but keeping the class proportion, in two sets: train (80%) and test (20%). After that we trained an ensemble of 11 models using Mordelet's algorithm and evaluated the sensitivity and the amount of negatives in U . This last metric is calculated as the specificity but taking into consideration that does not exist a real ground truth for unlabelled/negatives. We repeated 100 times the same random experiment to get different partitions of train and test and reported the mean and 95% confidence interval of the metrics.

Algorithm 1 Mordelet's Inductive bagging PU learning**INPUT:** P ; U ; K = size of bootstrap samples, T = number of bootstraps**OUTPUT** a function $f : \chi \rightarrow \mathbb{R}$

```

1: for  $t = 1$  to  $T$  do
2:   Draw a subsample  $U_t$  of size  $K$  from  $U$ .
3:   Train a classifier  $f_t$  to discriminate  $P$  against  $U_t$ .
4: end for
5: return  $\frac{1}{T} \sum_{t=1}^T f_t$ 

```

3. Results

The results of the experiment are summarised in Table 2. The algorithm can identify almost every patient with obesity, obtaining a sensitivity of 98%. Also, it estimates that the U contains around 18% of persons with an obesity condition, which is similar to the estimations reported by the WHO.

Table 2. Experimental results over 100 iterations using PU Learning

Metric	Mean	Confidence Interval 95%
Sensitivity	0.981	0.981, 0.982
Estimated negatives in U	0.822	0.820, 0.823
Estimated positives in U	0.178	0.177, 0.180

4. Discussion

As seen in the previous section, almost every obesity case presented to the algorithm is recognised correctly, presenting a 98.1% of sensitivity. The amount of negatives in U identified by the algorithm is around 82%, which means that the 18% of the patients in U are obese. These numbers are coherent with the statistics reported by the WHO. The results are relevant because, aside from being promising, no negative samples are required to train the model and the result was obtained with a relatively large N (49805).

The main contribution of this work consists in the application of one known machine learning algorithm to the identification of patients with obesity using a small fraction of labelled data. This solution could be useful to identify obesity at the patient level and mitigate the under-representation of this condition among the EHR [4]. This algorithm could be used to implement an automatic tool used in workflow mining, comorbidities statistics and screening, providing hospitals with a rapid method for detecting patients target for a program or intervention related to obesity.

The main weakness of this method is its bias to ignore obese patients that have made little use of the hospital resources. This effect is due to the variables

used to make the models, which are based mostly on the frequency of visits to specialist and diagnosis.

As future work, the most straightforward way of profiting this model is its implementation as part of a web-based platform, allowing users to send their data to get the predictions from the model and some statistics at the end of the interaction.

5. Conclusion

The implementation of the PU Learning methodology in the obesity identification produced satisfactory results, providing high sensitivity and identifying a similar number of patients with obesity to the WHO data. This model can be used to identify patients with obesity among the hospital's population to prepare interventions or public policies.

Medical Informatics in the Digital Personalized Health and Medicine Era: A SWOT Analysis and Actionable Strategies

Rada HUSSEIN^{a,1}

^a *Ludwig Boltzmann Institute for Digital Health and Prevention, Austria*

Abstract. With the rapid proliferation of digital health technologies, the role of medical informatics in advancing personalized healthcare and wellbeing is emphasized. To examine the readiness of medical informatics for fostering digital health moving forward, a Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis was performed. As a result, actionable strategies have been identified to maximize the benefits of medical informatics and overcoming the faced challenges in the digital health era.

Keywords. Digital health, medical informatics, strategic planning, SWOT

1. Introduction

The movement from "eHealth" to "Digital Health" emphasizes on providing people-centred and integrated health services utilizing the technological advances, such as mobile health (mHealth), Internet of Things (IoTs), Artificial Intelligence (AI), big data analytics, cloud computing, blockchain, etc. [1].

Medical Informatics or Biomedical and Health Informatics (BMHI) has become an established scientific-multidisciplinary discipline involving computer, cognitive and social sciences [2]. BMHI utilizes health information technologies to provide the optimal use of information for improving individual health, healthcare, public health and biomedical research.

The goal of this paper is to analyze the strengths, weaknesses, opportunities and threats (SWOT) of the current status of the BMHI field. Consequently, actionable strategies are identified to leverage the anticipated potential of BMHI for the Digital Health (DH) era.

2. SWOT analysis and actionable strategies

SWOT analysis is one of the world's most widely used methods for strategic planning [3]. This paper uses this instrument to match the strengths and weaknesses of the BMHI field with opportunities and threats of DH. The SWOT analysis has been performed

¹ Corresponding Author, Rada Hussein, E-mail: rada.hussein@dhp.lbg.ac.at.

based on the review of literature, industry reports and initiatives of the global health agencies.

To identify the potential tactical strategies for maximizing the benefits of BMHI for the DH era, an extended "variant" version of the SWOT-named the Threats, Opportunities, Weaknesses and Strengths (TOWS) analysis was conducted [3]. Figure 1 depicts how to develop actionable strategies through the TOWS analysis.

Figure 1 TOWS analysis and actionable strategies

3. Medical informatics strengths and limitations

The BMHI domain has a broad scope with the full range of knowledge (research) and practice (applications) [4] covering several sub-disciplines, mainly: bioinformatics, imaging informatics, clinical informatics and public health informatics. Additionally, there are two rapidly growing domains within the BMHI field, namely: 1) Consumer Health Informatics (CHI) that addresses consumers' articulated needs with managing their health concerns [4,5], and 2) Global Health Informatics (GHI) that focuses on empowering people to use appropriate technology, aligning with a global perspective of healthcare provision to all [6].

The main limitations of scaling up the eHealth initiatives and reaching the desired impact are [6]: 1) limited interoperability with legacy systems at national scale, 2) lack of evidence regarding the eHealth impact on health system performance and individual health, 3) lack of regulatory framework concerning data privacy and security, and 4) the insufficient use of large sets of data, i.e., converting data into health intelligence. On the other hand, the main barrier that hinders CHI [4,5] is the misalignment between the used technology and the users' socio-technical environment. This can significantly impact the technology utilization, endorsement by healthcare providers and users' empowerment.

4. Digital personalized health and medicine opportunities and challenges

The DH domain is considered as a key enabler of the personalized, preventive, predictive, participative, and precision (5P) medicine through leveraging the vision of providing equitable and person-centred care [5]. Consequently, DH has been attracting great interest of all stakeholders, including academic researchers, consumers, global health agencies, healthcare industry, policymakers and others. Recent studies covered different aspects of the DH domain, for example, industry and academic reviews of the DH technical trends [1], the World Health Organization (WHO) 's practical guide for monitoring and evaluating digital health interventions as well as the draft version of the global strategy on digital health 2020-2024 [7], Stanford medicine's

report on the democratization of healthcare [8], Johns Hopkins' roadmap for digital health validation [9], and a framework for assessing the impact of connected health services [10]. At the regulatory level, the Integrating Healthcare Enterprise (IHE)-Europe published its perspective in understanding and adopting the General Data Protection Regulations (GDPR) [11]. Additionally, a vision of how the GDPR supports healthcare transformation is described in [12].

Nevertheless, the main challenge facing the DH market [5,13] is that it is like "wild west" because most of the applications are neither based on the evidence of effectiveness nor adopting existing technical standards. Furthermore, most of the DH applications are mainly technology-driven as "one-size fits all" that may lead to harmful use. At the integration level [5,13], there is a lack of interoperability between user-generated data and health records in addition to an inadequate or fragmented legal frameworks, especially in the area of privacy and data security. Moreover, there is a mandate to address the DH from the socio-technical and organizational perspectives [1] in the context of change management, user engagement, information governance, workforce capacity, citizen empowerment, regulations, business models, etc.

5. Medical Informatics and digital health TOWS analysis

Table 1 summarizes the results of the SWOT analysis and their translation into TOWS analysis and actionable strategies.

6. Medical Informatics and digital health actionable strategies

As listed in Table 1, the actionable strategies can be categorized as follows:

The SO actionable strategies aim to *shape the BMHI research and education* for the DH era utilizing the advances in science and technology. This also matches with the proposed research agenda described in [2].

The WO actionable strategies aim to *build interdisciplinary partnerships and collaborations* to tackle the pressing challenges in aligning the BMHI field with future trends in medicine and DH technologies.

The ST actionable strategies aim to *leverage the role of the BMHI associations in building the ecosystem for DH connected health* with all involved stakeholders, including researchers, consumers, global health agencies, DH industry, standard development organizations, policymakers and others.

The WT actionable strategies aim to *roadmap an integrated future for BMHI and DH* at technical, environmental and organizational levels. This requires interdisciplinary teamwork of healthcare providers, informaticians, data scientists, systems developers, consumers, and experts in behavioural science, law, human-computer interaction, business modelling, and change management.

Table 1. BMHI and DH TOWS analysis and corresponding actionable strategies

	BMHI Strengths (S) S1 Breadth and diversity of BMHI subcategories S2 Wide scale of BMHI methods, tools and applications S3 Consumer Health Informatics articulates the user-centric approach S4 Global Health Informatics focuses on improving healthcare systems and outcomes	BMHI Weaknesses (W) W1 Too many overlapping standards hinder interoperability W2 misalignment between the used technology and the "real world" socio-technical environment W3 Limited large-scale evidence W4 Limited convergence of data into health intelligence at national and global scales
DH Opportunities (O) O1 Wide scale of technological innovation in big data analytics, cloud computing, AI, wearable devices, IoT, blockchain, etc. O2 Future trends in medicine: personalized, pervasive, predictive, preventive, participatory, precise, preemptive, and patient-centralized (8P medicine) O3 The WHO global health initiatives for digital health, universal health coverage, democratization of data, evidence for all, sustainable development goals, etc. O4 Great interest of the BMHI community (academia, industry and associations) worldwide in digital healthcare transformation	SO actionable strategies: SO1 Strengthen the BMHI discipline with new trends in medicine and technology (S1, O1, O2) SO2 Establish strong partnerships for international collaborative research programs and initiatives (S1-S4, O1-O4) SO3 Align the BMHI education and research programs with the WHO global health initiatives (S3, S4, O3) SO4 Leverage the strengths of the BMHI national and international associations in developing and updating the BMHI competencies frameworks (in regular basis)- that are intended for curriculum development, accreditation and workforce certification (S1, O4)	WO actionable strategies: WO1 Take the initiative (by the international standards organizations) to coordinate their efforts in improving the existing BMHI standards and resolving the interoperability gaps (W1, O1, O2, O4) WO2 Adopt socio-technical systems theory to support a better understanding of end-user performance (W2, O1, O2, O4) WO3 Adopt the WHO guidelines on DH interventions and corresponding frameworks for DH monitoring and evaluation (W3, O1-O4) WO4 Establish international scale research programs (that adopt new methodological or technical approaches) to advance interdisciplinary understanding (W4, O1-O4)
DH Threats (T): T1 Rapid pace of technology-driven applications (as one size fits all) T2 Lack of international regulatory frameworks for DH testing, validation, safety, and data privacy and security T3 Lack of interoperability standards for user-generated data T4 Low acceptance and adoption of DH	ST actionable strategies: <i>Leverage the role of the BMHI associations to:</i> ST1 Engage all stakeholders in designing national DH connected health services and the corresponding consumers' empowerment programs (S1, S2, T1, T4) ST2 Establish multidisciplinary taskforce to validate the current initiatives of DH regulatory frameworks in addition to technical working-groups to resolve the interoperability gaps with standards development organizations (S1-S4, T2, T3) ST3 Develop a specialized competencies framework for implementing and monitoring the DH regulatory framework (S1,T2) ST4 Develop a collaborative online platform for sharing best practices and lessons learned in overcoming the DH challenges across the associations' members (S1-S4, T2, T3, T4)	WT actionable strategies: <i>Overcome weaknesses by making them strengths (move toward SO strategy)</i> <i>Leverage the role of the BMHI associations to:</i> WT1 Develop a specialized competencies framework for DH open data and science (W1, W3, W4, T1, T3) WT2 Build a multidimensional collaborative team to develop a roadmap for interdisciplinary understanding of the DH socio-technical and organizational environment (W2, T2, T4) WT3 Develop a collaborative online platform for open innovation to tackle the DH challenges (W3, W4, T1, T4) WT4 Utilize change management concepts to 1) tackle the unpredictable and complex interactions between the people and DH technology, 2) strengthen user engagement (W2, T2, T4)

7. Conclusion

Medical informatics is expected to play a pivotal role in the transformation of digital "personalized" healthcare and medicine. To achieve this goal, the described actionable strategies support paving the way of the BMHI field towards the DH era, through 1) enriching the BMHI research and education agenda with emerging DH technologies, WHO initiatives and medicine trends, 2) strengthening the role of the BMHI associations in building the ecosystem of digitally connected health, and 3) road-mapping an integrated interdisciplinary future of BMHI and DH at socio-technical and organizational levels. Thus, realizing the BMHI aim in advancing science and improving healthcare outcomes.

Abstract. HUMIRA, a biologic therapy, has been approved to treat autoimmune diseases and been marketed in many countries worldwide. Much like other medications, it demonstrates many effects on the human body. It is important to understand its effects from the information generated by its users, and social media is one of the venues its users share their experience with the medication. To understand what HUMIRA effects were reported on Twitter, we utilized a relational similarity-based approach to infer HUMIRA effects based upon known medication-effect relations of other medications. With a corpus of 3.6 million preprocessed, “clean” tweets, a total of 55 effects were identified, and among them, 46 were previously observed, and nine were potentially unreported after verification with six reliable sources. The results not only indicate that many HUMIRA effects shared by the Twitter users are consistent with those previously reported, but also demonstrate the power and utility of our method, making it applicable to studying effects of other medications shared by Twitter users.

Keywords. HUMIRA, medication effects, mining social media, relational similarity, relation extraction

1. Introduction

As a blockbuster medication of AbbVie Inc., HUMIRA (adalimumab), a biologic therapy administered via subcutaneous injection, has been approved to treat autoimmune diseases in North America and the European Union as well as being approved in Japan for the treatment of intestinal Behcet’s disease. It has been sold in many countries worldwide, including Japan, China, Brazil and Australia [1]. Like other prescription medications, HUMIRA demonstrates various effects to those who took it, and its adverse effects such as serious infections and a rare type of cancer have been observed and reported [2]. With its broad use, it is important to understand how consumers share their experience of taking HUMIRA to help gain more insights into its effects directly from users of HUMIRA. Studies have shown that information shared by patients can be different from what was documented by healthcare professionals: a better understanding of adverse experience, better explanation of the nature, significance and consequences, and more detailed information [3].

¹ Corresponding Author, Keyuan Jiang, E-mail: kjiang@pnw.edu.

One potential source of obtaining user experience with medications is social media, including general-purpose platforms such as Twitter. A great number of efforts have been made in using social media as an alternative source of information for pharmacovigilance. As reported by Golder and colleagues in early 2015, more than 3000 published citations were found in their searches of research articles containing “social media” and “adverse events” [4]. Many published works focus on identifying expressions of medication and adverse effect concepts in the social media data, and little effort has been made in understanding the relations between medication and effect, yielding probably incorrect, false-positive or irrelevant results.

A number of semantic relations exist in the medical domain. The U.S. National Library of Medicine (NLM) compiled a collection of normalized semantic relations for biomedical literature², and many of them pertain to medication-effect relations such as *treats*, *causes*, *occurs_in*, *exhibits*, and *produces*. The SemRep software developed by NLM [5] extracts predicates from subject-predicate-object triples found in biomedical citations and maps them to the semantic relations. However, biomedical citations are written with closely followed grammatical and spelling rules, which is not the case for social media posts, in particular Twitter where these rules are not followed by its users to place needed text within the space limitation.

Identifying semantic relations between medication and effect from social media is a challenging task in natural language processing (NLP). Methods developed for formal writing do not perform satisfactorily with social media posts not following grammatical and spelling rules. Mikolov and colleagues reported that using relational similarity in the vector space model of neural embedding of text achieved state-of-art performance in many NLP tasks such as identifying syntactic and semantic relations [6]. To address the limitation, we devised a method of identifying semantic relations by finding the relations most similar to any known semantic relations. In other words, any pair of semantic relations share sufficient similarity is considered semantically similar, indicating that they have similar meanings. In the identified semantic relations between medication and effect, the effects associated with the relations are identified effects.

2. Method

Our relational similarity-based approach infers any potential relations of a study medication based upon their similarity to the known relations of other medications. For example, our method infers a relation of *Depakote: bad dreams* from the known relation of *Toprol XL: chest pain* for that there exists a similarity between the two medication-effect relations. Using this approach, we were able to infer the effects of HUMIRA. Described below are the steps of our pipeline of gathering, processing, analyzing data and validating the results.

2.1. Inference with Relational Similarity

Mikolov and colleagues suggested that in the vector space model, the relational similarity can be derived by computing the cosine value between the two relation vectors each of which is an offset vector of two-term vectors [6]. In our study, to compute the relational similarity, a vector space model was first learned from a corpus of unlabeled

² https://www.nlm.nih.gov/research/umls/META3_current_semantic_types.html

tweets with the help of word2vec software³, and each term, including medication and effect in the text corpus was represented as a real number vector. A medication-effect relation was represented as the offset of the medication vector and effect vector, and the similarity between the two offsets (relation) vectors was computed by the cosine value between the two vectors. Mathematically, we have $med_{base} : effect_{base} :: HUMIRA : effect_{potential}$ to represent the similar relations between two pairs of medication and effect. In implementation, $effect_{potential}$ is derived by finding the most similar effect vector to the result of $vector(effect_{base}) - vector(med_{base}) + vector(HUMIRA)$, where med_{base} and $effect_{base}$ are known and for all the medications except HUMIRA – that is, multiple known relations may be used to infer a single relation. A collection of HUMIRA effects was gathered by inferring all possible effects based upon all the known medication-effect relations of other medications.

2.2. Data

A corpus of 53 million unlabeled tweets related to a list of medication names including HUMIRA was collected by a self-made crawler for twitter.com. The tweets were posted in a time span from March 2006 to summer 2017. The collected tweets were preprocessed to remove any non-English and duplicate tweets. The preprocessed tweets were further filtered by a list of effect terms found in the SIDER database to ensure that each tweet contains HUMIRA and at least an effect expression so that both will appear within the window of the context, facilitating the inference. The resultant 3.6 million “clean” tweets were used to learn the Word2vec vector space model.

SIDER is an online resource of side effect information from marketed pharmaceutical products, and hosted and maintained by EMBL [7]. Its data of all known effects were utilized to filter preprocessed tweets. The SIDER’s effect data of each medication were used to come up with a collection of known medication- effect relations. SIDER has two distinct types of effects: side effects (SEs) and indications (INDs). One major advantage of the SIDER data is that each effect is associated with a UMLS Concept Unique Identifier (CUI), facilitating the expansion of effect concepts to include corresponding Consumer Health Vocabulary (CHV) terms.

2.3. Annotation

Inferred HUMIRA effects are the results of vector algebraic arithmetic, and the vector manipulations do not appear to be straightforward to comprehend in the semantic sense. Annotating related tweets can help us confirm that inferred effects (or relations) were actually mentioned in the Twitter posts. After effects were inferred, we expanded each effect concept by adding its corresponding CHV terms, and tweets containing both HUMIRA and the CHV-expanded effects were extracted from the corpus of “clean” tweets. The extracted tweets were annotated by one of the co-authors to label them as SE or IND based upon the semantics of the tweet text.

2.4. Verification

To uncover if any inferred effects were known or potentially unreported, we, in early 2018, checked the inferred CHV-expanded effects against six reliable sources: SIDER,

³ <https://code.google.com/archive/p/word2vec/>

FDA Dailymed, Fdable.com, MedlinePlus, PubMed, and Google Scholar. SIDER contained both side effects and indications of many marketed products, but it did not contain either for HUMIRA. FDA dailymed contains both side effects and indications. Fdable.com is a Web-search engine of FDA Adverse Event Reporting System (FAERS) data, containing adverse event data. MedlinePlus provides curated consumer health information and prescription and over-the-counter medication information. Both PubMed and Google Scholar helped us to verify if any HUMIRA were mentioned in any scientific publications. Any inferred effects found in any of the six sources were considered known, and those not found were considered potentially unreported.

3. Results and Discussions

Table 1. Statistics of inferred effects.

Count of Effects		Count of SE Effects	Count of IND Effects
Inferred	87	70	17
Annotated	55	44	11
Accuracy	0.632	0.629	0.647

As shown in Table 1, our relational similarity-based method generated 87 inferred effects, among which 70 were SE effects and 17 IND effects. After annotation, 55 effects were confirmed to have relevant tweets, among which 44 were SE effects and 11 IND effects, yielding an overall accuracy of 0.632.

Table 2. Statistics of inferred effects after annotation and verification.

Effects	Count of Inferred	Count of Known	Count of Unreported
SE	44	36	8
IND	11	10	1

After verification against six reliable sources, 46 out of 55 annotated effects were found to be previously reported, showing the consistency on these effects, and 9 of them were found to be potentially unreported, as shown in Table 2. It demonstrates the ability of our method to (1) correctly infer HUMIRA effects which had been previously observed and reported, and (2) infer effects potentially unreported previously. Being able to infer the known effects correctly indicates that our relational similarity-based method can discover existing effects similar to the known base relations. Capable of inferring potentially unreported effects are of special importance for pharmacovigilance in which the safety or suspected effects of pharmaceutical products are being continuously monitored and assessed. It was noticed that there is no entry of HUMIRA or adalimumab in the SIDER database, and this does not affect the inference of HUMIRA effects. Instead, it shows a unique power of our method: effects of any medications can be inferred whether their data exist in SIDER as long as the data for the study medications can be incorporated into the model.

Table 3. Example tweets of potentially unreported HUMIRA effects

Effect	CUI	Tweets
Ache	C0234238	had an overall <u>ache</u> after my humira shot...Thursday my Cellulitis infection came back.
Panic attacks	C0086769	Day 2 <u>panic attacks</u> and chest pain. Think new drug is freaking out my immune system. #IBD # Humira
Swellings	C0013604	Again humira day and got huge swelling around injection site anyone else get this ??? 

Table 3 lists a few example tweets relevant to the HUMIRA effects inferred by our method. Not only do they mention both HUMIRA (the medication) and effects, but they do show the semantic relations between both. Any potentially unreported effects of HUMIRA discovered by our method warrant further assessment or clinical investigation. They may serve as the foundation of developing a hypothesis of suspected effects to help advance pharmaceutical knowledge, medical science, and clinical practice. It is known that misspellings of medication names and side effect concepts are common in Twitter posts [8, 9]. Covering broad linguistic variations of tweet text is one area of improvement for this project, and it may help discover more HUMIRA effects from Twitter posts.

4. Conclusion

In this work, we investigated mining HUMIRA effects mentioned in Twitter posts using our relational similarity-based method, and we were able to identify effects previously known and potentially unreported, demonstrating the power and effectiveness of our relational similarity approach. We believe that our pipeline of gathering, processing, and analyzing data is applicable to identifying the effects of many other medications mentioned in Twitter posts, to gather user-generated information on medication effects.

Abstract. Financial losses in Medicaid, from Fraud, Waste and Abuse (FWA), in the United States are estimated to be in the tens of billions of dollars each year. This results in escalating costs as well as limiting the funding available to worthy recipients of healthcare. The Centers for Medicare & Medicaid Services mandate thorough auditing, in which policy investigators manually research and interpret the policy to validate the integrity of claims submitted by providers for reimbursement, a very time-consuming process. We propose a system that aims to interpret unstructured policy text to semi-automatically audit provider claims. Guided by a domain ontology, our system extracts entities and relations to build benefit rules that can be executed on top of claims to identify improper payments, and often in turn payment policy or claims adjudication system vulnerabilities. We validate the automatic knowledge extraction from policies based on ground truth created by domain experts. Lastly, we discuss how the system can co-reason with human investigators in order to increase thoroughness and consistency in the review of claims and policy, to identify providers that systematically violate policies and to help in prioritising investigations.

Keywords. Healthcare fraud, ontology-based information extraction, claims auditing

1. Introduction

Improper payments for Medicaid in fiscal year 2018 were estimated at 9.8% of Medicaid spending (\$36.2 billion) [1]. Examples of improper payments include billing for services exceeding permitted unit limitations, billing separately for services already included in a global fee (unbundling) and billing for medically unnecessary services. Regulations around compliance and accurate billing are described in federal and state policies. Armed with a deep understanding of these policies, FWA investigation units aim at identifying violations in claims submitted for reimbursement by medical providers. However, the sheer volume of claims, benefits, and policy to review, combined with the limited investigation resources and varying skill sets of

¹Corresponding Author: Theodora S. Brisimi, E-mail: theodora.brisimi@ibm.com

²We would like to acknowledge Pierpaolo Tommasi, Carlos Alzate, Spyros Kotoulas, Fabrizio Cucci, Tim Cooper, Mark Gillespie, Mark Gilroy, Jonathon Ryan, Grace Ferguson, John Davis and Jillian Scalvini for their support and insights for this work.

investigators, lead to poor coverage and understanding of the opportunity landscape. The Centers for Medicare & Medicaid Services have developed a fraud detection system that analyses claims to identify providers with suspicious billing patterns [2]. This and similar approaches rely on a combination of applying data analytics techniques to patterns in structured claims data [3, 4] and hand-crafting rules that flag sets of claims for additional investigation. The system presented in this paper focuses on fusing policy and claims together to identify improper payments. It achieves this by semi-automatically converting policy text into *benefit rules*, which are applied directly to claims. This approach is novel to the best of our knowledge and presents a number of research challenges, including:

- a) *Domain modelling & knowledge extraction*: Key to our system is building an ontology that is flexible enough to capture the diversity and complexity of the policy *benefit rules* as well as expressive enough to represent the knowledge in a simple, unambiguous and human-readable way to support policy comprehension and human oversight. The ontology is used to integrate relevant terminology and heterogeneous domain sources (e.g., state programs, eligible places of service, coding systems, such as the International Classification of Diseases ICD-9/10 and corresponding updates), as well as to guide the information extraction.
- b) *Linking of policy information to the claims data*: Some elements of the *benefit rules* can be easily mapped to claims data columns (e.g., a minimum age constraint will be linked to the birth date of the patient), while others require a more complicated process (e.g., aggregated units of service for a given patient over a given period). The system also needs to map services described in policy to their representation form used in claims, such as the Healthcare Common Procedure Coding System (HCPCS).
- c) *Rules polarity*: In policy documents, benefit rules usually express what will be reimbursed (a *positive* rule), e.g. "Adults at high risk for caries may have up to 2 units of dental prophylaxis per year". Sometimes, they express what will not be reimbursed (a *negative* rule), e.g. "Dental prophylaxis is not a covered benefit for children aged 0-4". This provides a challenge for automated identification of improper claims because while the negative rules are generally unambiguous and directly identify violations, the positive rules are often ambiguous and incomplete. In the example, we must infer that more than two units are not allowed for a high-risk adult and that there may be an implied rule for non-high-risk adults and separate rules for children and high-risk children.
- d) *Validation of the approach*: Validating the feasibility and impact of our system when used as part of the investigators' workflow requires constructing a set of ground truth rules to evaluate its performance and measuring its generalizability across different policy areas as well as geographic regions.

2. Method

Below we present the components that comprise our system. Fig. 1 runs an example through the end-to-end pipeline.

Policy Ingestion: This component converts the PDF policy document into an HTML document ³, and further enriches the HTML with information identifying sentences, and their hierarchical arrangement (e.g., grouping sentences under a common header or identifying a paragraph introducing a list).

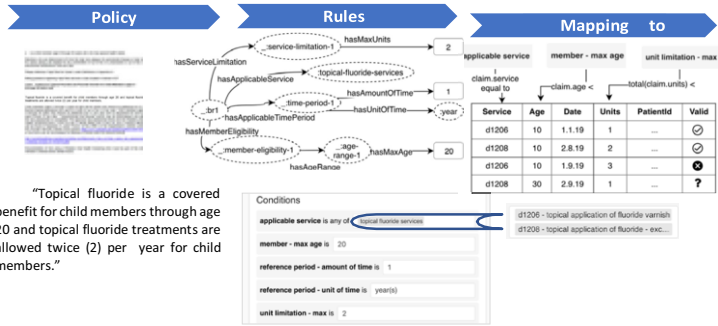

Figure 1. Proposed system's pipeline overview with *benefit rule* extraction and claims validation example.

Rules Extraction: This component is an ontology-based information extraction system based on the enriched HTML policy. Two extractors are implemented on top of two different NLP technologies: Watson X [5] and SystemT [6]. For each textual fragment, the extraction involves the annotation of medical concepts and relations guided by UMLS and the domain ontology. We construct a machine-processable representation of a benefit rule by reasoning over the ontology and translating textual patterns into ontological entities and corresponding relations. Each extracted rule is represented in a knowledge graph (KG). The rule extraction process may generate multiple KGs from the same textual fragment(s), which can be consolidated based on different strategies. Human oversight of this extracted knowledge is essential to correct any errors and establish trust. To that end, we transform each KG into a user-friendly representation, that contains conditions and corresponding values (e.g., *applicable service* with value *topical fluoride* or *maximum age* with value 20). This empowers the investigators to interact with, adapt and use the extracted knowledge. Rules in policies follow different templates that we captured in the ontology working together with FWA investigators. A detailed discussion of the ontology creation is presented in [7]. The extracted *benefit rules* are then normalised, i.e., properties values are standardised, so that rules execution can unambiguously identify them in claims. The normalisation steps include linking extracted services to specific procedure codes, e.g., *topical fluoride treatments* maps to codes *D1206* and *D1208*, and representing dates in a standard format, e.g., representing *fiscal year* as the appropriate dates range depending on the geographic area.

Mapping to claims: The conditions of each *benefit rule* must be mapped to claims columns in order for the rule to be executed. We assume a claims schema against which the mapping is performed. Examples of mappings are: direct - e.g., a minimum age property in the rule maps directly to an age column that can be calculated from the birth date of the patient and the date of service, aggregations - e.g., a rule that places an upper limit on the number of claims over a period of time. To map this to claims, we need to (i) filter claims, e.g. by service, (ii) group claims, e.g., by patient or date and (iii) compute the aggregation, e.g. an incremental count of claims, value-dependent - e.g., a rule may have a 'requirement' element with values such as 'prior authorisation', 'medical necessity', etc. Each of these values may map to distinct columns in the claim data.

³IBM Compare and Comply: www.ibm.com/watson/developercloud/compare-and-comply/

This component applies the *benefit rules* to claims and outputs a status for each claim: improper, correct or unknown, with the latter representing claims that are not represented by any rule. Claims that appear to be improper are linked automatically to both the executed benefit rule and the relevant policy documentation.

3. Results and Discussion

We designed a prototype investigation workbench (Fig. 2) that highlights the impact of bringing policy and claims data together into a unified workflow. Using this workbench, investigators can contrast what providers are authorised to do with what they actually do. This starts by selecting a policy area (e.g., topical fluoride) and the policy sections (rules) to be investigated (Fig. 2: #1, #2). An Investigator can then immediately visualise, inspect and prioritise claims that appear to be out-of-sync with that policy (Fig. 2: #3,#4).

This helps in addressing significant problems in investigation planning and execution: (1) investigators can size potential recovery opportunities before deciding where to allocate scarce resources; (2) maintaining a direct connection between policy and related claims helps build a water-tight case for recovery; (3) automatically showing the relevant claims (and claim fields) for a policy area under investigation saves time by reducing dependencies on other departments for pre-defined data extracts/spreadsheets; and (4) it enables investigators to review and correct the automatically-extracted benefit rules (Fig. 2: #2), thereby building up a shared store of high-quality, executable policyknowledge.

We validate the rules extraction performance via precision and recall. To create Ground Truth (GT) for these measurements, we used a set of documents for Physical Therapy policy from one U.S. state, plus Dental policy from two U.S. states. For each one, a team of three FWA Investigators manually translated the associated benefit rules into a computable form, based on our ontology (**GT rules**). Automatically **extracted rules** were then compared to these, yielding the evaluation results presented in Table 1.

Table 1. We pair a GT rule R with the set of extracted rules from the same text, and we compute a pairing score that takes into account the number of common conditions and values. If the pairing score is always zero, then R is a false negative. Otherwise, the true positive corresponding to R is the extracted rule having the maximum pairing score. Details on the pairing score calculation can be found in [7]. The last column of the table shows the average maximum pairing score across all rules.

Policy	num. GT rules	num. extracted rules	precision	recall	avg. pairing score
Physical Therapy	25	38	0.58	0.88	0.61
Dental (State 1)	50	46	0.65	0.60	0.69
Dental (State 2)	34	42	0.64	0.79	0.56

The ontology used in the experiments comprises of 35 classes, 1151 individuals, 29 properties and 4214 lexicalisations (i.e., ontology entity labels used to annotate textual entities). We are currently extending our work to improve the breadth and coverage of the models and the extraction, in particular across paragraphs, headings and in cases where there are conflicting extracted information. Most of the effort required to generalise across domains and geographical areas is on identifying external (instance) area-specific data to be incorporated into the ontology, such as programs and grouping of codes that are not

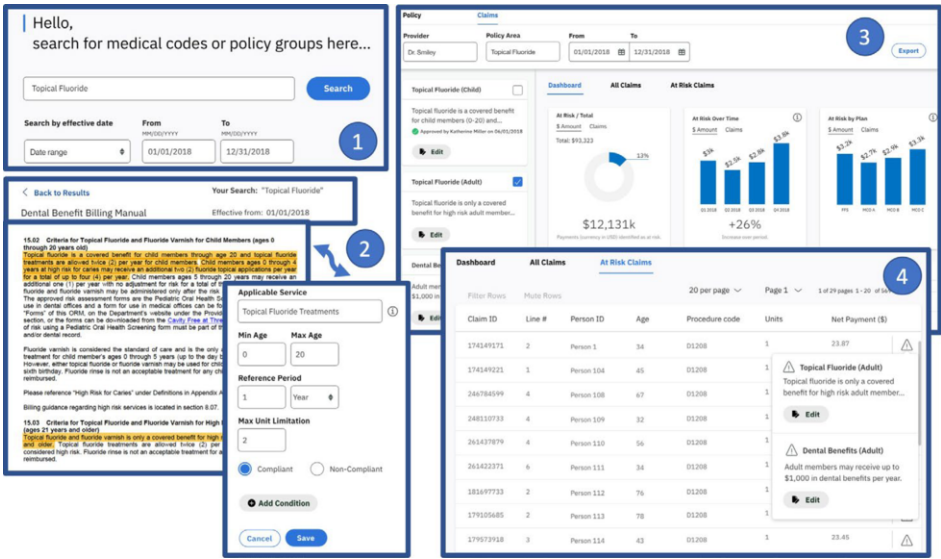

Figure 2. Workflow: The investigators receive a phone tip about a suspicious dental provider *Dr. Smiley* and decide to look for violations related to topical fluoride. Next, they 1) search for related policies, 2) select one or more extracted rules from these policies and modify/correct the automatically extracted rule(s), if necessary, 3) define the scope (e.g., provider and date range), and apply the set of rules to the related claims, seeing the impact of the violations in terms of number of improper claims and potentially recoverable amount of money, 4) carefully inspect each improper claim and the corresponding policy it appears to violate.

part of a global (e.g., federal) code set. Without these groupings, for example, considering the *Dental (State 2)* policy, recall started at around 0.59. When clinical vocabularies such as UMLS are used to find services, treatments and diagnoses, recall increases to 0.76 (with a precision of 0.68). Furthermore, when 135 different groupings of codes were added by a coding expert, recall improved to 0.79, with a small drop in precision to 0.64 (Table 1).

Abstract. The Swiss Variant Interpretation Platform for Oncology is a centralized, joint and curated database for clinical somatic variants piloted by a board of Swiss healthcare institutions and operated by the SIB Swiss Institute of Bioinformatics. To support this effort, SIB Text Mining designed a set of text analytics services. This report focuses on three of those services. First, the automatic annotations of the literature with a set of terminologies have been performed, resulting in a large annotated version of MEDLINE and PMC. Second, a generator of variant synonyms for single nucleotide variants has been developed using publicly available data resources, as well as patterns of non-standard formats, often found in the literature. Third, a literature ranking service enables to retrieve a ranked set of MEDLINE abstracts given a variant and optionally a diagnosis. The annotation of MEDLINE and PMC resulted in a total of respectively 785,181,199 and 1,156,060,212 annotations, which means an average of 26 and 425 annotations per abstract and full-text article. The generator of variant synonyms enables to retrieve up to 42 synonyms for a variant. The literature ranking service reaches a precision (P10) of 63%, which means that almost two-thirds of the top-10 returned abstracts are judged relevant. Further services will be implemented to complete this set of services, such as a service to retrieve relevant clinical trials for a patient and a literature ranking service for full-text articles.

Keywords. Precision medicine, literature, variant, terminology, text-mining

1. Introduction

After several years of collaboration to improve and harmonize the NGS (next-generation sequencing) practices in somatic mutation calling, a number of Swiss hospitals, pathology institutes and the Swiss Institute of Bioinformatics members have pointed to a set of shortcomings, most prominently the lack of a central repository for clinically verified variant annotations in cancer. To support the harmonization of variant annotation in diagnosis, to provide a centralized curated database of somatic variants coming from Swiss hospitals, and to enable a seamless interaction between participating institutes and global initiatives, the Swiss Variant Interpretation Platform for Oncology (SVIP-O) was developed [1].

* contributed equally

The curation of variants is a labour-intensive process. First, NGS analyzes result in a huge amount of variants in the patient sample. Second, for each variant, many sources must be consulted, including the scientific literature. While for some already well-studied variants (e.g. BRAF V600E), identifying a set of relevant scientific literature is not an issue, for variants of uncertain significance (VUS), the task can be more difficult. Indeed, the curator must comprehensively gather the relevant literature to assign a standardized tier level (ASCO/AMP/CAP guidelines), in which the variant, the gene or the diagnosis could have been labelled in different ways [2]. Thus, the curator must author multiple queries to avoid missing out on an important paper. Moreover, when large sets of literature are available, triage of the literature (i.e. selection of relevant papers as well as rejection of irrelevant papers) can be a very time-consuming task [3].

Therefore, we developed a set of text analytics services intended to facilitate and improve the comprehensive collection of literature to support further processing steps, which will include the capture of textual evidence by Swiss-Prot curators and clinical validation by medical specialists for final storage in the SVIP-O knowledgebase. First, we developed a service to annotate the clinically relevant information contained in the scientific literature. This service enables not only to accelerate searches (i.e. queries are performed using unique identifiers in a standardized field) but also to increase the recall (i.e. the annotation step conflates synonyms and string variants). However, the annotation of variants faces a serious limitation: no universal terminology is available. In order to offset this issue, variants can be searched in literature using synonym expansion. Thus, as a second task, we propose a service to expand a variant name with a set of expressions, including Human Genome Variation Society (HGVS) standard descriptions for the protein, transcript and genomic DNA levels, but also non-standard formats found in the literature (e.g. V-600-E or BRAFV600E) [4]. Finally, a service collecting and prioritizing literature is available: it combines heterogeneous information retrieval results for an optimal article triage, which altogether can reduce the triage effort by a factor of 3 [5].

2. Methods

Our MEDLINE and PMC collections consisted of respectively 30,415,832 and 2,632,396 documents (in January, 7th 2020), daily updated and loaded into a MongoDB document database and then into an ElasticSearch index.

2.1. Recognition of terminological entities in the literature

The collection was annotated with codes from various terminologies and ontologies, such as neXtProt [6] for genes, Drugbank [7] and WHO-ATC [8] for drugs, NCI Thesaurus [9] and ICD-O-3 [10] for diseases, and HPO (Human Phenotype Ontology) for phenotypes. Querying MEDLINE through annotations is not only faster because the indexes are pre-computed but also it results in a better recall as each occurrence of a concept receives one unique ID for all its synonyms. We also applied string pre-processing methods. For instance, if dashes are present, they are treated to form a “new” word (e.g. “AB-C” becomes “AB”, “C” and “ABC”). Papers which contain only the word without dash will thus be retrieved.

2.2. Generation of synonyms for variants

While many databases of polymorphisms and variants exist, such as ClinVar, COSMIC or dbSNP, using those resources as terminologies is fairly challenging. They describe variants using a standard nomenclature recommended by the HGVS [11]. These standards require a precise syntax and a reference sequence on which the variation is described to avoid uncertainty about the position of the change. Both of them are rarely observed in publications. Depending on the database, variants entries are also centered on different levels: genomic, transcript or protein, which are not true synonyms.

Therefore, we developed our own synonym generation tool that enables us in addition to annotate variants not necessarily present in those databases. Our efforts focused until now on SNPs. Our tool generates synonyms given a gene and a variant. It includes a validation step, where we check whether the given base or amino acid exists at the given position. Then, we compute the description of the variant at the other levels, using the Mutalyzer tool [12]. We finally generate synonyms with many syntactic variations as encountered in the literature [4]. We also extend the search to all possible mutations in the case the replacing amino acid is not defined.

2.3. Prioritization of literature

The report focuses on the literature triage tasks, i.e. the ability to rank MEDLINE abstracts - as opposed to full-text articles - to support further curation steps. Triage is usually performed on abstracts, whose content is sufficient to help a domain expert to decide whether a particular report needs in-depth reading or not.

Our literature prioritization system is based on two steps: collecting a complete set of abstracts and reranking the MEDLINE set. A most complete set of abstracts related to a particular triplet (i.e. a variant in a gene for a specific diagnosis) is built by the intersection of several queries' output: normalized entities (i.e. gene and diagnosis) are searched with unique identifiers within the MEDLINE annotations, while a keyword search expanded with synonyms is performed within free texts from MEDLINE for not normalized entities (i.e. variant). Moreover, a set of queries, with decreasing levels of specificity (e.g. abstracts not mentioning diagnosis) is also performed. Results are linearly combined with previous abstracts set. Then, we apply different strategies to re-rank the MEDLINE set: 1) based on the number of occurrences of some annotated entities (e.g. abstracts mentioning drugs); 2) based on demographic information; 3) based on a set of keywords that should (e.g. treat) or should not (e.g. marker) be present in the abstracts and 4) based on the breadth of treatments returned in the top articles. The last re-ranking strategy aims at avoiding that all top returned articles are related to the same treatment, but rather favoring abstracts that are discussing different treatment options.

The system is evaluated following standard TREC procedures using TREC PM 2019 benchmarks [13], comprising 40 synthetic patient cases, each consisting of a disease, a variant, a gene and some demographic information.

3. Results

3.1. Recognition of terminological entities in the literature

Thanks to our annotations, we are able to retrieve more papers than classical queries on PubMed. The query *BRAF* retrieves 14,099 papers on PubMed versus 14,952 papers on our index with his corresponding code *NX_P15056*. Another example, query *non-small cell lung cancer* retrieves 51,858 papers on PubMed versus 70,972 (code *C2926*) with our index. These results are explained by expansions provided with annotations: synonyms (*BRAF1* or *RAFB1*; *NSCLC*) and processing of hyphens (*B-RAF* becomes *BRAF*, thus a paper containing *B-RAF* will be retrieved). Table 1 represents an overview of annotations which are available for our collections for some of the terminologies.

Table 1. Extract of statistics about annotations on MEDLINE/PMC collections obtained in January 2020.

Type	Terminologies	No of entities annotated in	
		MEDLINE	PMC
Drugs	DrugBank	80,100,2684	86,769,820
Drugs	ATC	46,173,559	30,404,688
Diseases	NCIt	131,577,959	108,049,190
Diseases	ICD-O-3	4,837,713	2,955,200
Genes	neXtProt	36,320,459	91,930,787
Total annotations		785,181,199	1,156,060,212
Average per document		26	425

3.2. Generation of synonyms for variants

Our tool generates 42 synonyms for a given valid variant when successfully mapped to all levels, with 16 synonyms for protein variant, 13 for transcript variant including COSMIC id and 13 for genomic variant including dbSNP id. It increases the retrieval between a few percent and several times the number of publications depending on the variant frequency, with smaller effect for very popular variants. For instance, 708 additional abstracts, over 1715, are retrieved for the variant V617F in JAK2.

3.3. Prioritization of literature

Precision at rank 10 (P10) has been used to evaluate our system. This metric reflects the proportion of relevant documents retrieved in the top ten results. Our system resulted in a P10 of 63%, which means that almost two thirds of the top-10 returned abstracts are judged relevant. This service is publicly available: <http://candy.hesge.ch/Variomes/>.

4. Discussion

We have thus developed a set of services that can be used to facilitate the process of variant curation and validation by physicians, and in particular molecular pathologists, oncologists and hematologists, as well as rare disease experts. The literature triage service, boosted by the variant expansion service and the MEDLINE annotations service, is able to reduce the search burden by simplifying the paper triage. Indeed, the system's

evaluation demonstrated that in the top-10 abstracts proposed by our system, more than six are relevant for the clinical decision-support task. In addition, such services can increase the possibility of finding a relevant paper. Although this aspect might be marginal for common variants, it is key for rare (or poorly studied) variants for which each publication matters. As an example, the search for the TP53 V143A variant in PubMed results in only seven abstracts, while our system is able to return 34 abstracts. Indeed, while PubMed strictly searches for V143A, our system is also able to search for Val143Ala or 428T>C.

Additional services will be implemented to complete this set of services, such as a literature ranking service for full-text articles. Indeed, scientific abstracts reporting on treatments do not always mention all the information regarding diagnosis, gene and variant, so that full-text articles are needed, as well as supplementary data when available. A service to retrieve relevant clinical trials for a given patient is also under development, enabling to connect patients with experimental treatments.

^c Department of Neurology, University Hospital of Münster, Germany

Abstract. Consumer wearables can provide objective monitoring of movement disorders and may identify new phenotypical biomarkers. We present a novel smartwatch-based prototype, which is implemented as a prospective study in neurology. A full-stack Machine Learning pipeline utilizing Artificial Neural Networks (ANN), Random Forests and Support Vector Machines (SVM) was established and optimized to train for two clinically relevant classification tasks: First, to distinguish neurodegenerative movement disorders such as Parkinson's Disease (PD) or Essential Tremor from healthy subjects. Second, to distinguish specifically PD from other movement disorders or healthy subjects. The system was trained by 318 samples, including 192 PD, 75 other movement disorders and 51 healthy participants. All models were trained and tested with hyperparameter optimization and nested cross-validation. Regarding the more general first task, the ANN succeeded best with precision of 0.94 (SD 0.03) and recall of 0.92 (SD 0.04). Concerning the more specific second task, the SVM performed best with precision of 0.81 (SD 0.01) and recall of 0.89 (SD 0.04). These preliminary results are promising as compared to the literature-reported diagnostic accuracy of neurologists. In addition, a new data foundation with highly structured and clinically annotated acceleration data was established, which enables future biomarker analyses utilizing consumer devices in movement disorders.

Keywords. Mobile applications, artificial intelligence, machine learning, movement disorders

1. Introduction

Movement Disorders as Parkinson's Disease (PD) are primarily diagnosed via clinical examination. A meta-analysis by Rizzo et al. 2016 indicated that the pooled diagnostic accuracy is at 73.8% for general neurologists, geriatricians, or general practitioners (95% Credible Interval (CRI): 67.8%-79.6%) and 79.6% (95% CrI 46%-95.1%) for movement disorder experts regarding initial assessment and 83.9% (95% CrI 69.7%-92.6%)

¹ Corresponding Author, Julian Varghese, Institute of Medical Informatics, University of Münster; E-mail: julian.varghese@uni-muenster.de

regarding refined diagnosis after follow-up [1]. It ascertains that the overall validity of clinical diagnosis did not improve in the last 25 years and new biomarkers are needed, ideally with high availability. We present a novel mobile prototype, called the smart device system (SDS), which has been implemented and approved for a two-year prospective study [2]. The system is the first one, which captures two-side synchronous acceleration data from smartwatches with the integration of electronic questionnaires to account for early symptoms, medication, medical and family history. Health informaticians and movement disorder specialists designed the system, including a smartphone app to guide the examination step by step. Previously, we have demonstrated the accuracy of raw measurement data and tremor frequency detection as proof of concept to visualize and detect subtle movement characteristics, which are imperceptible to human vision [3].

As a clinical use case, we trained a diagnosis classification model. To our knowledge, most of the related models (summarized in [4]) for PD deal with limited sample sizes ($n < 100$) and are overly restricted to classify PD vs healthy. However, in clinical practice, the neurologist does not only face people being exclusively a PD case or healthy case. Instead, there are many differential diagnoses with PD-similar symptoms. In these cases, the models mentioned above would not be applicable or would perform significantly poorer. To address this issue, an important disease category is part of the patient recruitment: movement disorders other than PD as essential tremor, atypical parkinsonism, secondary causes of parkinsonism, dystonia, which will be summarized as DD in the following. Our system is trained for two clinically relevant classification tasks. First, to distinguish between movement disorders (PD+DD) and healthy subjects. Such a system could potentially be used at home-based settings or at general practices, e.g. to indicate whether certain abnormal movement characteristics (e.g. hand tremor) is pathologic or still normal (e.g. physiological tremor). Second, to distinguish PD from the rest (DD + healthy), which addresses a setting in specialized practices.

2. Methods

Details of the study design, examination steps and feature extraction have been published previously [2]. Study participant's assessment starts with smartphone-based data entry on medication, current diagnosis, family history and early symptoms. The smartwatch-based examination consists of ten different coordination tasks, including serials seven to provoke and monitor different movement characteristics while seated in an armchair. Altogether, the examination takes 15 minutes. The system is composed of two smartwatches (Apple Watch Series 4) for two-hand acceleration measurement and two smartphones (Apple iPhone version 7) for electronic questionnaires, examination guidance, watch-pairing and data transfer. These devices are connected via one central iOS app on the master smartphone. Sampling rate of acceleration data in all three axes is 100 Hz. Each sample is pseudonymized and ready for real-time visualization and further data processing [3]. Table 1 summarizes the three aforementioned relevant study participants categories PD, DD and Healthy. The full list with demographic details and years of disease onset is provided for each sample in the supplement. It also includes diagnosis details of the DD cluster [5]. All diagnoses were confirmed by neurologists and finally reviewed by one senior movement disorder expert. The current stack of the data analytics pipeline is implemented in Python, illustrated in Figure 1 and includes

Artificial Neural Networks (ANN), Random Forests and Support Vector Machines (SVM) as the three main classifiers.

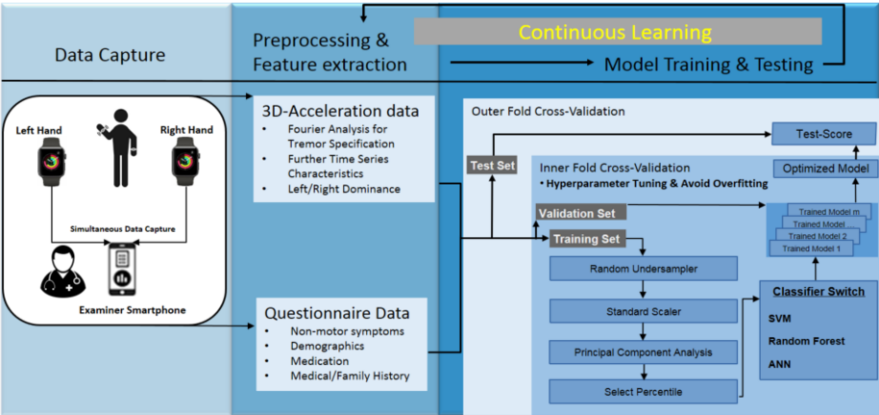

Figure 1. Data Analytics pipeline. ANN = Artificial Neural Networks, SVM= Support Vector Machine.

Table 1. Class population.

Class	Sample Size	Average Age (SD)
PD	192	65.71 (9.61)
DD	75	60.88 (15.58)
Healthy	51	60.45 (14.22)

TSFresh 0.12.0 is used to extract a series of general-purpose time-series characteristics [5]. Moreover, acceleration data is processed with Fast Fourier Transform to extract tremor frequencies. Amplitude-Histogram analyses are applied and checked for dominances on the left or right-hand side. A complete list of all extracted features and descriptions is given in the supplement [6]. The set of features is trained with nested cross-validation using five inner and five outer folds. During one inner fold, we applied the random undersampler from Scikit Learn 0.21.3 [7] in order to remove the bias towards the majority class by randomly removing samples of that set. The standard scaler from Scikit Learn subtracts the mean and scales to the unit variance for every feature. The principal component analysis (PCA) reduces the dimensionality without assuming independence. The Scikit Learn-based 'Select Percentile' step randomly selects a subset of features, which are then used for training the classifier. While the standard Scikit Learn library implements SVM and Random Forests, the ANN is implemented with dense multi-layered perceptron networks using the KERAS 2.2.4 package and Google's Tensorflow 1.3.1, which provides full GPU support [8]. The whole process of model training and testing is wrapped by Photon-AI, a hyperparameter optimization toolbox [9]. During an inner fold, we optimize the hyperparameters for the PCA, the Select Percentile and the classifiers. We used the Scikit Learn's grid-search optimizer as our optimizer. A list of the full hyperparameter space is provided in our supplement [6].

3. Results

Tables 2 and 3 list the best performing models for each of the three classifiers after nested cross-validation. While the ANN performed best for the first task regarding average accuracy of 0.89 and precision of 0.94, the SVM – using radial basis function (RBF) as kernel – performed best in the second task with accuracy of 0.79 and precision of 0.81. None of the different classifiers outperformed the others when taking the overlap of their corresponding standard deviations into account. Details on all optimized hyperparameter values and best performing features are provided in the supplement [6]. Further classifiers, including deep neural networks, are being evaluated and discussed in the next section.

Table 2. Average Performances for general classification task: Parkinson's and related movement disorders vs Healthy. SD= standard deviation. Rbf= Radial Basis function.

Estimator	Accuracy (SD)	Precision (SD)	Recall (SD)	F1 (SD)
ANN	0.89 (0.00)	0.94 (0.03)	0.92 (0.04)	0.93 (0.00)
Random Forest	0.88 (0.04)	0.91 (0.04)	0.95 (0.04)	0.93 (0.02)
SVM - rbf	0.89 (0.03)	0.92 (0.03)	0.95 (0.04)	0.93 (0.02)

Table 3. Average Performances for specific classification task: PD vs. Other related movement disorders and Healthy.

Estimator	Accuracy (SD)	Precision (SD)	Recall (SD)	F1 (SD)
ANN	0.77 (0.04)	0.78 (0.04)	0.90 (0.06)	0.83 (0.03)
Random Forest	0.75 (0.03)	0.75 (0.03)	0.91 (0.04)	0.823 (0.02)
SVM - rbf	0.79 (0.01)	0.81 (0.01)	0.89 (0.04)	0.85 (0.01)

4. Discussion

The more general task was evaluated with precision and recall above 90% for all classifiers, which highlights potential applicability in non-specialized settings as home-based assessment or general practices. Regarding the more specific task, the average diagnostic accuracy (79%) of the best performing model is higher than pooled reported accuracy of general practitioners and comparable to movement disorder experts regarding initial assessment [1]. A number of machine-learning approaches share a major disadvantage as they are trained by retrospective data sources, with high data quality, which however might be illusory at real-time or point of care. A major strength of our mobile system is that it only requires the self-generated data from the 15 minutes examination being not dependent on any further patient data or external information systems. Thus, we are confident that our results are reproducible in prospective scenarios. The reported results still need to be taken with caution as our setting comes with general limitations: The study is conducted at a single site, and thus we cannot rule out bias due to specific site population, examination setting or target diagnoses. We recruit from a large tertiary care centre and include all types and stages of Parkinson's disease and other movement disorders, and therefore, we believe the training data provides a suitable data foundation to start from. However, as a matter of our recruitment

setting, only a minority of samples are Parkinson's cases with early disease stage, which would be the ideal population to train from. After study completion, a multi-centric study design is planned for 2021, which would include different outpatient clinics and home-based assessments. At the current state, the system is to be used for scientific purpose only as it is not cleared as a medical device.

We have tested several approaches towards Deep Learning with recurrent networks as Long-Short-Term Memories. Their performances were remarkably poorer, being not significantly higher than random guessing. Our sample size may not be sufficient (e.g. > 10,000) to train a deep network that requires substantially more model parameters. As our data-preprocessing steps evolve and the sample size grows, we are monitoring different types of Neural Networks and further traditional statistical models. Apart from the machine-learning framework, the highly interactive research platform enables researchers to visualize objective movement characteristics and to have a deeper look at subtle characteristics within a hundredth of a second. In a previous study, we could visualize tremor characteristics imperceptible to non-sensor-based human vision [3]. This could unveil further morphological features in the future, which are not yet utilized.

To conclude, we have generated a sensor-based data foundation to study movement characteristics in a broad area of different movement disorders. Machine Learning classifiers show high accuracy for distinguishing relevant diagnoses classes compared to expert-based performances. Further research is underway to show generalizability of the system.

Abstract. The rapid improvement in mobile health technologies revolutionized what and how people can self-record and manage data. This massive amount of information accumulated by these technologies has potentially many applications beyond personal need, i.e. for public health. A challenge with collecting this data is to motivate people to share this data for the benefit of all. The purpose of this study is to survey and examine factors that may motivate sharing this data. We asked 447 participants four questions related to health data sharing and motivation. Participants with a chronic disease were concerned about data sharing but also willing to share health data if personalized feedback is provided. Functionality, ease of use, and privacy are regarded as crucial features of health apps.

Keywords. Public health, mHealth, motivation, health surveys, health data sharing.

1. Introduction

The ubiquitous nature of smartphones, wearables, and sensors have revolutionized the way people collect health-related data. An increasing number of people collects large amounts of data for disease-management, fitness, and self-surveillance. In a recent study, more than 60% of American participants tracked various health parameters, including diet, weight, and physical exercise, where 21% relied on fitness tracker technology [1]. People with chronic diseases use different technologies, e.g. mHealth apps and continuous glucose monitors for diabetes management, collecting and processing health data for their self-management. This data can potentially be used as a secondary source of information for public health, including tracking of disease trends, behavioural patterns over time, chronic diseases status, research, and policy work [2, 3, 4, 5]. The impact of these self-collected data highly depends on people's willingness to share their data for the intended purpose. Considering the potential of these data to inform about individual and population health, understanding the users' expectations and willingness towards mass data sharing is an important area of research. Various factors could affect people's motivations to engage in mass data sharing, e.g. lack of trust, which is mainly

¹ Corresponding author, E-mail: andre.henriksen@uit.no ; * Authors contributed equally

subject to data security, privacy, and confidentiality issues [6]. When sharing such data, expectation and willingness often differ in different patient groups, as well as in healthy people [7, 8], e.g. people with type 1 diabetes have a high need to record health data several times per day. Here, we examine factors related to people's knowledge and expectations toward raising motivation for sharing of health-related data and comparing these factors across different groups.

2. Method

We created an online survey with questions related to motivational factors around mHealth apps and data sharing. Questions were derived from 16 in-person interviews [6]. The survey was conducted among English-speaking internet users in a Swiss cohort of healthy people and also in English and Norwegian online diabetes groups. We collected data between 11/2018 and 08/2019. The questions related to data sharing are: 1) How concerned are participants about sharing health data, 2) what do participants expect in return when sharing health data, 3) which data types are participants willing to share anonymously for research, and 4) how important are different criteria in order to agree to install an application that collects and shares data from their wearable device. Options were on a 4-point Likert scale from "not important at all" to "very important" (including "I don't know"), or multiple-choice. We stratified responses into three groups: 1) People with diabetes (PWD), 2) people with other chronic disease and 3) people without a chronic disease. Details about the questionnaire are available at DataverseNO [9]. We report descriptive statistics on age, gender, experience using wearable devices and mobile health apps and wearables for sharing health or activity data.

3. Results

Four hundred forty-seven (447) participants finished the survey, of which eight did not answer whether they have a disease, and nine selected "Do not want to answer". Further analyses are based on the remaining $N=430$. Sixty-one (61) participants had diabetes, 82 participants had another chronic disease, and 285 had no chronic disease. The majority of participants came from Switzerland (187), Norway (59), US/UK/Australia/Canada (77), France (26), and Germany (13). Remaining 46 came from 35 countries covering all continents. Table 1 gives their demographics, familiarity with mHealth apps, and sharing experience. There was no age ($p=.083$) or gender ($p=.133$) difference between the groups. However, 97% in the diabetes group use a wearable device for collecting activity or other health data, compared to only 51% in the "no disease" group, and 55% in the "other chronic disease" group, $\chi^2(423)=44.04$, $p=.001$. Many PWD has experience in sharing data, less so people without a chronic disease, $\chi^2=19.6$, $p < .001$.

Table 1. Demographics and familiarity with mHealth apps. Na= no answer.

	With diabetes	With other chronic diseases	Without chronic disease
Age: <30 y; 30-50y; >50y	15; 17; 27 (Na: 2)	9; 32; 40 (Na: 1)	34; 96; 146 (Na: 6)
Gender: female; male; other	35; 25; 1	59; 20; 3	177; 99; 3
Wearable device: yes; no	59; 2	44; 36	143; 137
Sharing experience: yes; no	24; 27 (Na: 10)	22; 45 (Na: 14)	47; 160; (Na: 11)

3.1. Technologies use for health tracking

87% of those with diabetes use a health-specific device, in addition to often using a Physical Activity (PA) tracker. 3% use no sensor or wearable device. Among those with other- or no chronic diseases, the use of sensors integrated in the smartphone and PA trackers are most common. 25-30% use mobile health apps. Generally, participants preferred to discuss health issues with health providers. PWD would discuss it with others PWD (17%), but rarely with their family (6%). This is in contrast to persons with other- or no chronic disease, where 19% and 20%, respectively, would discuss health issues with their family and friends, see Figure 2b. This difference with whom to share was statistically significant, $\chi^2=34.67$, $p<.001$.

3.2. Concerns about data sharing

Regarding what people are most concerned about sharing health data, persons with no chronic disease are in general least concerned, and all three groups rate storage as least and transparency as most concerning. Figure 1a shows how each group rate concerns about confidence and trust, data ownership, storage location/availability, and transparency of third party usage. Figure 1b shows how important certain features are for each group in order to agree to install an application that collects and share health data from their wearable device.

Figure 1. a: Concerns about different aspects of data sharing. b: Importance of features, answer option 1 to 4.

3.3. Participants expectations for sharing health data

Regarding what participants expected in return for sharing their health data, personalized feedback was chosen by 60% of participants, integrated view (i.e. aggregated results), was chosen by 53%, decision support by 36%, and least chosen (16%) was comparing

status with others. There was no difference between the groups in their expectations, smallest $p > .74$, but comparing with others was rated as least important (Figure 2a).

Figure 2. a: Expectations for sharing data. b: Group distribution of health tracking technology.

3.4. Willingness to anonymously share given data types in a research project

Groups do not differ in sharing lifestyle/dietary information, signs of infection, daily mood, geographical location, sleep duration, social environment (corrected for multiple comparisons). Participants are least willing to share their geographical location. Persons with chronic disease are more willing to share medication intake, physiological indicators and their weight. An overview is given in Table 2.

Table 2. Overview of willingness to share specific health data by group. Chr. = chronic.

	Medication intake and treatment	Lifestyle/ dietary intakes	Signs of infection	Physiological indicators	Daily mood	Physical activity	Geographical location	Sleep duration	Weight	Social environment	None of these
N	213	219	195	202	193	248	87	240	221	173	89
Diabetes	53	41	31	46	29	43	20	43	43	30	5
Other chr.	44	45	45	40	46	54	16	50	49	35	16
No chr.	116	133	119	116	118	151	51	147	129	108	68
X ²	43.48	9.05	5.22	24.39	5.73	8.93	6.92	8.29	15.48	2.87	7.59
p-value	<.001	.011	.074	<.001	.057	.012	.031	.016	<.001	.238	.023

3.5. Features' importance in mHealth app

Regarding which features of a health-app is important to participants (1=not important to 4=very important), non-disturbed tracking and automatic setup is rated by most as important, i.e. the main effect of feature, $F(3.83, 1163.75)=3.389$, $p=.01$, $\eta^2=.011$. All features were more important to people with a chronic disease, $F(2, 304)=12.09$, $p<.001$, $\eta^2=.074$. PWD rate automatic data collection as most important, yielding a significant interaction effect, $F(7.66, 1163.75)=2.104$, $p=.035$, $\eta^2=.014$.

4. Discussion

Mass sharing of health data could provide vital information for individual health management and public health. Continuous collection of quality health-related data and willingness to share these are limited by the user's motivation and expectations. The rate of acceptance of health tracking devices among clinicians is increasing [10], but

retention is decreasing [11]. Compared to PWD who use wearable sensors, participants with no- and other chronic disease reported higher adoption of sensors integrated in the smartphone and PA trackers. Automatic data collection, easier interface, e.g. voice command, tailored and personalized feedback is likely to increase usage and long-term engagement in such devices.

Concern about health data sharing is dependent on the type of data, and related concerns on issues such as privacy, security, confidentiality, transparency, and ownership. Participants with no chronic disease are less concerned compared to people with a chronic disease. Indeed, potential consequences of data leakage like repeated low blood glucose level (hypoglycemia) might result in the suspension of one's driving license or disqualification of health insurance enrollment in some countries. Some privacy and security shall be kept, i.e. many participants do not want to share their geographical location.

This study on how to motivate health data sharing is a collaboration between several projects where different systems for health data collection are under development. Results from the present study, and upcoming publications on related topics, will be used to direct the implementations of these systems for maximum acceptance. Future works include data collection, data quality and accuracy analysis, and detecting health patterns at the population level and in people with specific chronic diseases. Fulfilment of participant's expectations and resolving individual concerns could motivate sharing health-related data. Results indicate that participants expect some kind of immediate benefits from sharing their data, including tailored and personalized data analysis, integrated view, feedback and others. Comparison of status among peers was found to be less relevant.

A Path Towards Inclusion: Transdisciplinary Experience for the Inclusion of Self-Perceived Gender in an Information System

Melanie CASSARINO^{a,1}; Eunice CORREA^a; Sebastián MINOLETTI^a; Amalia BOTTO^a; Romina RAPISARDA^a; María Florencia GRANDE RATTI^a; Daniel LUNA^a

^a*Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*

Abstract. In Argentina, since 2012 the Gender Identity Law guarantees that people who identify as transgender must be called by their chosen name, among other things. Transgender patients are usually not represented in information systems, whether electronic or not. This can place them in situations of vulnerability and discrimination. With that in mind, an interdisciplinary team was formed to take address the problems of this population regarding to the information systems of Hospital Italiano de Buenos Aires. The aim of this study is to spread the experience of the transdisciplinary team on the Electronic Health Record's modification and other associated applications to achieve include the self-perceived gender identity and the chosen name of those people who modified their gender.

Keywords. Transgender, Electronic Health Record, User-centered design, prototype

1. Introduction

In health systems it is common that people who identify with a different gender or name than the one that was assigned to their birth, suffer discrimination [1] by both administrative and healthcare staff. According to a survey conducted by INDEC and INADI in 2012 [2], three out of ten transgender or transvestite women present stories of abandonment of medical treatment due to discrimination in health institutions. For the same reason, five out of ten, stopped going to hospitals. The same study also indicates that a significant barrier to access the health system is the lack of coverage. It is estimated that 80% of this population does not have access to health insurance or prepaid medicine [3].

Gender identity is understood as “the internal and individual experience of gender as each person feels it, which may or may not correspond to the sex assigned at the time of birth, including the personal experience of the body. This may involve the change of the appearance or body function through pharmacological, surgery or other methods, when it is freely chosen. It also includes other gender expressions, such as dress, speech and manners” [4]

According to a study carried out by Fundación Huésped in 2011 [5] about the perceptions and experiences of stigma and discrimination in populations of trans

¹ Melanie Cassarino, [E-mail: melanie.cassarino@hospitalitaliano.org.ar](mailto:melanie.cassarino@hospitalitaliano.org.ar)

women, men who have sex with men and drug users, it was found that trans women were the most systematically excluded group from an early age and that their social welfare was below expectations due to stigma and its consequences, such as the legal non-recognition of their identity.

In 2012, Law 26743 of "Gender Identity" [4] is sanctioned in Argentina, which defines in its Article n°1 that every person has the right:

To the recognition of their gender identity;

To the free development of his person according to his gender identity;

To be treated accordingly to their gender identity and, in particular, to be identified in this way in the instruments that prove their identity regarding to the name, image and sex with which it is registered there.

The Ministry of Health of the Argentinian Republic, issued a "Guide for health teams" on comprehensive health care for transgender people [6]. This guide mentions that people must be respected in their name and gender of choice within the health system, both with respect to the physical place of hospitalization and in the registration instruments (medical history, certificates, records, etc.).

There's plenty bibliography about the inclusion of sex, gender and chosen name in in electronic health records [7][8][9][10][11][12][13][14]. Reviewing all of these papers, we could agree that there is a general consensus that these changes can positively affect this population's quality of care and medical attention.

1.1. Situation in Hospital Italiano de Buenos Aires

The Hospital Italiano de Buenos Aires (HIBA) it is a private hospital, of high complexity that has 780 beds, 40,000 hospitalizations per year and more than 2 million outpatient consultations. Within its structure is the Department of Health Informatics that develops the information systems within the institution. Since 1995, the Hospital has an electronic information system that covers both the assistance and administrative and management areas. The department is responsible both for the design of the tools and also for the storage's optimization and information retrieval with the aim of increasing patient safety, reducing error and increasing quality of care.

The HIBA has an application for the registration of patients. In 2017, with the objective to apply Law 26743 to the Master Patient Index (MPI), it was decided to develop a modification in it [15] with the aim of include the different identities that coexist in the Argentine territory as well as the use of the chosen name for people identification.

Analyzing the current bibliography and the sanctioned Argentine law, the possibility of registering the following items within the MPI was added:

- Chosen name
- Self-perceived gender identity (with structured fields: Man, Woman, Trans - man, Trans - woman, Intergender, Other)

After the implementation of the change in the registration system, the work team raised the need to include this information into the Electronic Health Record (EHR) so that the self-perceived gender identity and the chosen name are available to all healthcare professionals.

Because of that, the Department of Health Informatics is currently working on the visualization of this new information in the different available applications: from the patient caller system located in the waiting rooms, to Electronic Health Record, where

health professionals will have a comprehensive record that will allow them to provide holistic healthcare.

The aim of this study is to spread the experience of the transdisciplinary team on the EHR's modification and other associated applications to achieve the inclusion of self-perceived gender identity and the chosen name of those people who modified their gender.

2. Methods

In the meetings held with the healthcare team that take care of the trans population, the following needs were detected:

- View the name chosen as well as the name that appears on the National Identity Document (DNI).
- Known the person's biological sex and self-perceived gender.
- Identify which organs related to biological sex the person has [16].
- Identify what surgeries or hormonal treatments the person received [17].

The Health Informatics work team decided to divide these needs into two work stages;

First stage: within this first stage, we worked on the visualization of the people's identification information (chosen name, DNI name, biological sex and self-perceived gender) in the different applications.

Second stage: it was defined to focus the second stage of work on the needs related to clinical care: organs, surgeries and hormonal treatments of patients.

In this study we will focus mainly on the description of the work done during the first stage of the project.

Based on the need detected in the healthcare staff to be able to visualize the identification information of the people, it was decided to carry out the card sorting technique in a random way to different people from the HIBA (nurses, physicians, administrative staff). This technique is used to investigate how users think that information on digital products should be organized and / or categorized. Because the HIBA's EHR has iconography to represent the gender of the patients, for this work, the "card sorting" technique was used to identify the knowledge that the staff had about the icons that represent trans and intergender identity. After this process, we proceeded to choose the icon that represents the transgender population of Argentina to be included in the EHR.

Then, different prototypes of the EHR that contemplate the person's chosen name, the surname corresponding to the DNI and the initials of the DNI name in parentheses, were designed.

Structure: [First name + last name + (initials first name + initials last name)] (Figure 1)

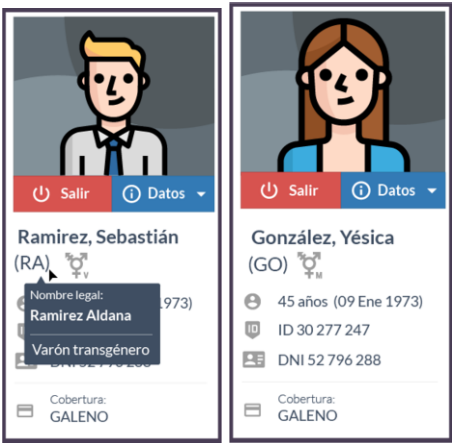

Figure 1. Representation in the EHR

These designs were prototyped and tested with end users who were unaware of this project. This process will be published in another research paper.

As part of the inquiries and while the design was being made for the EHR, a meeting was held with representatives of the Health Secretariat of the Argentine LGBT Federation (FALGBT) in order to showing them the prototype created for the EHR and the election of iconography for gender representation.

During this meeting the FALGBT provided advice on the visualization of information, privacy/confidentiality of data and information regard to trans and intergender identities. They considered that the presented prototype was adequate to represent transgender identities. Also, they suggested continuing with the second stage (detailed above) in order to integrate this information with the patient's clinical information.

3. Conclusions & Discussion

Throughout this process, we re-discovered the importance of teamwork and the added value that interdisciplinarity gives. Having user-centered design specialists and health professionals with informatics orientation within the team, allowed a holistic vision when devising the solution for the correct identification within the EHR.

Besides it was very important the opportunity to have meetings with health professionals at the time of making the inquiries, validating the information and being able to detect their needs to continue the path towards inclusion.

Our next step is to incorporate a list of surgeries, hormonal treatments and other clinical data relevant to the care of this population.

A Systematic Review on CDSS Alert Appropriateness

Olufisayo OLAKOTAN^{a,1}, Maryati MOHD YUSOF^b and Sharifa EZAT WAN PUTEH^c

^{a, b} *Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia*

^c *Faculty of Medicine, Univerisiti Kebaangsaan Malaysia*

Abstract. Clinical decision support systems (CDSSs) provides vital information for managing patients by advising clinicians through an alert or reminders about adverse events and medication errors. Clinicians receive a high number of alerts, resulting in alert override and workflow disruptions. A systematic review was carried out to identify factors affecting CDSS alert appropriateness in supporting clinical workflows using a recently introduced framework. The review findings identified several influencing factors of CDSS alert appropriateness including: technology (usability, alert presentation, workload and data entry), human (training, knowledge and skills, attitude and behavior), organization (rules and regulation, privacy and security) and process (waste, delay, tuning and optimization). The findings can be used to guide the design of CDSS alert and minimise potential safety hazards associated with CDSS use.

Keywords. CDSS, Alert fatigue, Alert override, Framework, Appropriateness, Clinical workflow

1. Introduction

Clinical decision support systems (CDSS) has widely been implemented to improve care quality, patient safety, reduce costs and enhance healthcare outcomes [1]. CDSS encompasses various tools such as automated alerts and reminders that provide its users with information that can enhance clinical decision making [2] through evidence-based recommendations to clinicians at the point of care [3]. Despite the wide adoption of CDSS, clinicians receive numerous alerts, leading to a phenomenon known as ‘alert fatigue’ [4]. These alerts are meant to avoid possible safety risks, such as drug-drug interactions (DDI) and allergies.

However, clinicians override relevant and irrelevant alerts, which may lead to adverse events or unintended patient harm. A significant reason for alert override is disruption in clinician’s workflow [5]. Therefore, evaluating the appropriateness of CDSS alerts and its effect on workflow enables us to understand how alerts can be triggered effectively to support clinical workflow. This paper presents a systematic review on factors affecting CDSS alert appropriateness in supporting clinical workflow.

¹ Corresponding Author, E-mail: P84271@siswa.ukm.edu.my.

2. Theoretical background

The new framework for evaluating CDSS alert appropriateness in clinical workflow is proposed based on critical review and adaptation from previous health information technology framework including Human-Organization-Technology-fit (HOT-fit) [6,7], Human Automation and Interaction (HAI), [8], business process management (BPM) life cycle [9], and Systems Engineering Initiative for Patient Safety (SEIPS) [10] (Figure 1).

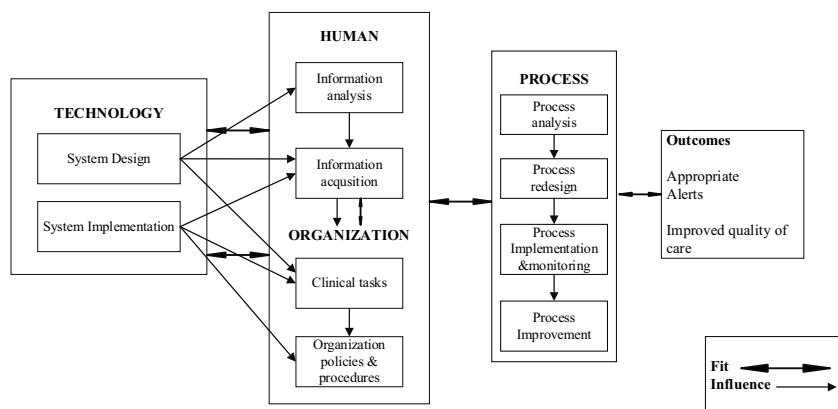

Figure 1. CDSS appropriateness framework

3. Methodology

This review seeks to answer “what are the factors affecting CDSS alert appropriateness in supporting clinical workflow?”. The review followed the guidelines of Preferred Reporting Items for Systematic Reviews (PRISMA). Bibliographic databases namely PubMed, Scopus, ACM, Science Direct, IEEE, Ovid Medline, and Ebscohost, were searched for relevant literature from 1997 to 2018. The search was conducted on October 11, 2018 to February 28, 2019. The following keywords such as clinical decision support system (CDSS), alert fatigue, alert override, electronic health record (EHR), electronic medical record (EMR), health information system (HIS), were used to search the databases. We included studies on features and functions pertinent to CDSS alert appropriateness and alert and workflow related problems in healthcare settings. Studies on medical devices with alarms and beeps, such as physiological monitors, ventilators, and pumps, were excluded. A quality assessment tool known as Critical Skill Appraisal Program (CASP) for qualitative, quantitative and retrospective study was used to evaluate the quality of the selected articles.

The bibliographic databases returned 9769 publications. Then, 8899 titles and abstracts were initially screened, and 7796 were excluded. In summary, 76 papers were obtained (64 main papers and 12 additional papers from citation chaining). Deductive data analysis was conducted based on the proposed evaluation framework dimensions and measures, whereas inductive analysis enabled us to identify new themes and sub-themes such as knowledge base, alert flexibility, alert content and workload which are categorized under system design and implementation dimensions.

4. Results

Table 1 highlights key factors affecting CDSS alert appropriateness in supporting clinical workflow.

Table 1. Factors affecting CDSS alert appropriateness in supporting clinical workflow

Technology	Human	Organization	Process
System design	Information acquisition	Policy and procedure	Process analysis
Alert content (N = 14)	Knowledge and skills (N = 5)	Privacy and security (N = 5)	Waste (delay (N = 6); others (N = 6))
specificity/ sensitivity (N = 7)	Training (N = 5)	Rules and regulations (N = 3)	Process redesign
Usability (N = 7)	Information analysis		Modification (N = 7)
Alert presentation (N = 7)	Perception (N = 7)		Process mapping (N = 1)
Alert flexibility (N = 7)	Behavior (N = 6)		Process implementation
Knowledge base (N = 5)	Attitude (N = 3)		Automation (N = 9)
System implementation			Process monitoring/ improvement
Workload (N = 8)			Bottleneck (N = 7)
Hardware and software (N = 7)			Tuning and optimization (N = 4)
Documentation (N = 6)			
Communication (N = 6)			

Technology. Usability problems such as illegible screens, excessive mouse clicks and poorly designed drop-down menus that are counter-intuitively arranged, disrupts clinician’s workflow [11,12]. Moreover, alert fatigue and override persists because alerts do not indicate severity levels (i.e., mild, moderate and severe) [12]. Alerts should contain reliable and clear text messages that can inform or enhance clinician’s decision making. Studies reports that knowledgebase problems such as poorly categorized codes and wrongly configured default settings contributes to adverse events and medication errors [13,14]. Therefore, CDSS rules, codes, and default settings must be properly modified to present accurate and up-to-date information to users during patient care [14]. Poorly implemented CDSS has created additional problems for busy clinicians such as workload, data entry burden, system downtimes, hardware and software breakdown [1,14]. For instance, system is down when the hardware and software cannot handle transaction loads [1]. Software malfunctions such as outdated versions of operating systems and system lockout hindered clinicians from entering and verifying orders [14,15]. Successful implementation of CDSS requires a proper understanding of clinician workflow to ensure the fit between them.

Human. Inadequate knowledge and skills hindered clinicians from using CDSS with its alert function effectively [1,16]. For example, incompetent clinicians cannot create, view, and adjust reminders (e.g., removing inapplicable reminders). Clinicians without any formal training or education on how to use CDSS might engage in self-learning, which leads to alerts misinterpretation [1,15]. However, most clinicians agree that hands-on training will improve their skills in handling CDSS [14,16]. Clinician’s attitude towards alerts depends on how alerts are displayed (i.e. intrusive or interruptive) during workflow [17]. CDSS alert that provides irrelevant information can subconsciously change prescriber’s behavior during prescription [5].

Organization. Flawed organizational policies and procedures can contribute to CDSS failure and workflow disruption. Hospital rules and regulations resulted in rigid task execution such as inability to adjust alert settings [17], tedious process of overriding password and justifying alert override prior ordering [18]; inability to access most CDSS features due to the security measures [19]; conflicting alerts; [20]; and silenced low-level alerts for drug-drug interactions (DDI) [21].

Process. Delays caused by system downtime impedes patient flow and disrupts clinician's workflow [22]. Examples include a lockout system feature that hindered clinician from ordering medication, resulting delays in prescribing medication; switching between screens and overriding alert caused non-value added activities (i.e. waste); [23]. Monitoring recurring errors and identifying bottlenecks such as alert fatigue, alert overload during the clinical process will minimize workflow disruption [13]. In addition, tuning and optimization strategies such as the use of alert evaluation dashboard to monitor alert override rates or physician response to alerts will prevent recurring errors and subsequently enhance clinician's workflow [23].

5. Discussion and conclusions

This review evaluated CDSS alert appropriateness that was mostly contributed by technology factors, particularly system design that is related to alert content, accuracy, and usability. Process factors are the second highly influencing factors where waste, including delay, and bottleneck from the use of CDSS alert required process modification and redesign to improve workflow efficiency. Human factors reported negative user perception and behavior towards CDSS alerts that are highly influenced by poor system design, followed by inadequate skills and training. Disruptive CDSS alerts that affect clinical processes were highly reported. Therefore, CDSS must be well designed to support clinical tasks, workflow, and cognitive activities and aligned with the socio-technical aspects. Organizational policies and procedures should be flexibly adapted to accommodate CDSS implementation. Continuous process improvement methods such as BPM and Lean can be implemented to identify and eliminate inefficient clinical processes impeding the fit between technology, human, organization. Our findings indicate the usefulness of the proposed evaluation framework in addressing alerts and workflow problems in clinical settings. Future studies should address cognitive work challenges or activities that impede the use of CDSS alerts.

Abstract. *Background and objective:* Social media could be valuable tools to support people with multiple sclerosis (MS). There is little evidence on the MS-related topics that are discussed on social media, and the sentiment linked to these topics. The objective of this work is to identify the MS-related main topics discussed on Twitter, and the sentiment linked to them. *Methods:* Tweets dealing with MS in the English language were extracted. Latent-Dirichlet Allocation (LDA) was used to identify the main topics discussed in these tweets. Iterative inductive process was used to group the tweets into recurrent topics. The sentiment analysis of these tweets was performed using SentiStrength. *Results:* LDA identified topics were grouped into 4 categories, tweets dealing with: related chronic conditions; condition burden; disease-modifying drugs; and awareness-raising. Tweets on condition burden and related chronic conditions were the most negative ($p < 0.001$). A significant lower positive sentiment was found for both tweets dealing with disease-modifying drugs, condition burden, and related chronic conditions ($p < 0.001$). Only tweets on awareness-raising were most positive than the average ($p < 0.001$). *Discussion:* The use of both tools to identify the main discussed topics on social media and to analyse the sentiment of these topics, increases the knowledge of the themes that could represent the bigger burden for persons affected with MS. This knowledge can help to improve support and therapeutic approaches addressed to them.

Keywords. Multiple sclerosis, Twitter, natural language processing, sentiment analysis, topic modelling

1. Introduction

Multiple Sclerosis (MS) is the leading cause of non-traumatic neurological disability in young adults [1]. In order to successfully self-manage such a chronic condition, patients require to learn about and manage their symptoms and problems [2-4]. Moreover, they also need social support that enhances the awareness that they are cared for.

Social support is known to be an important aspect for persons with MS (pwMS) [5-7]. However, problems in societal participation, such as reduced interactions with family or friends, are common among people affected by this condition due to physical

¹ Corresponding Author: Guido Giunti E-mail: Guido.Giunti@oulu.fi.

disabilities and MS fatigue [8]. In this sense, the ubiquity of social media and their great potential to engage and communicate with others could make these channels valuable tools to support pwMS [9-10]. PwMS using social media could benefit from communities that share content linked to positive sentiment, as positive emotion motivates cooperation [11]. However, there is not much evidence on what are the topics being discussed on social media related to MS, and if these topics are linked to positive sentiment, and therefore could provide the needed social support.

The objective of this work is to identify the main topics related to multiple sclerosis that are discussed on Twitter, and to analyse the sentiment polarity linked to these topics.

2. Methods

We collected tweets from Twitter using the Twitter API matching the query: #ms OR #multiplesclerosis OR "multiple sclerosis" that were posted between February 9th 2019 and June 26th 2019, and were in English language.

In order to identify the topics discussed in these tweets, we utilized Latent-Dirichlet Allocation (LDA) [12]. LDA is a generative statistical model that assigns to each document (e.g., a single tweet) a probability to belong to each topic of a list of topics which number is fixed and usually small [13]. We pre-processed each tweet with the following steps: 1) All URLs were removed using the following regular expression: `https?://[[:alnum:]][:punct:]]*`; 2) All tweets were tokenized²; 3) All tokens were lemmatized using the R packages *textstem*³ and *lexicon*⁴; and 4) Tokens were filtered to remove stop words using stopword lists from R packages *lexicon* and *tm* [14] (English stopwords).

We built a document-term matrix from the lemmatized and filtered tokens of all tweets collected. Then we trained an LDA model using the 47,852 original English tweets posted between February 9th and May 2nd 2019 and 20 topics. We fine-tuned LDA hyper-parameters using a differential evolution algorithm [15] with R package *DEoptim* [16] with 200 iterations and a population size of 30. For each population member (a pair of values for hyperparameters) considered, an LDA model was generated using a random sample of 80% of the training data. The model was then evaluated computing the perplexity of the other 20% of the training data. At the end, we obtained hyperparameter values 0.292217 and 0.026492 that were used for the final model.

The sentiment analysis of the tweets was performed on the whole dataset (74,076 tweets) using SentiStrength [17]. This software is specially designed to analyse the sentiment in short texts by assigning two scores: the intensity of the positive sentiment (1 to 5) and the intensity of the negative sentiment (-1 to -5). To apply SentiStrength, all tweets were allocated in plain text file, which means that unicode special characters were removed from the original text. As a result of the analysis every tweet was assigned a positive and negative sentiment score.

³ <https://cran.r-project.org/web/packages/textstem/index.html>

⁴ <https://cran.r-project.org/web/packages/lexicon/index.html>

The treatment of personal information for this study was approved by the data-protection officer at the University Hospital of North Norway (Ref:02275).

3. Results

The API extracted a total of 74,076 original tweets (i.e., not retweeted) on MS written in English. The sentiment analysis showed an average positive strength of 1.6 (SD=0.8); and a negative strength of -1.78 (SD=1.0) on the extracted MS tweets.

The 20 topics identified with LDA were analysed and recurring themes were identified and grouped into 4 main topics through an iterative inductive process. These 4 topics dealt with: Related chronic conditions; Condition burden; Disease modifying drugs; and Awareness raising. Table 1 summarizes the main keywords identified with LDA and included in each of the topics.

Table 1. Recurring MS’ topics identified with LDA and grouped through iterative inductive process

Topic	Keywords included
Related chronic conditions	Autoimmune; autoimmune_disease; parkinsons; alzheimers; rheumatoid; rheumatoid_arthritis; chronic_illness; crwriter; neurodegenerative; mental; Gofundme; injury; nervous; nervous_system; spinal; central; spinal_cord; central_nervous; cord; brain_injury
Condition burden	Sign; ms_symptom; symptom_ms; quality_life; quality; warn_sign; sign_ms; sign_symptom; early_warn; risk_multiple; Cbd; cancer; marijuana; pain; dying; chronic_pain; bill; spasm; plea; cancer_multiple; Diagnose_multiple; diagnose; letsbeatms; intezaarnakaro_letsbeatms; inzaarnakaro; visit_intezaarnakaro; suffer_multiple; income; disability_progression
Disease modifying drugs	Cell; immune; sclerosis_patient; therapy; stem; trial; stem_cell; immune_system; disease_modify; phase; Drug; relapse; fda; approve; fda_approve; remit; treat_multiple; relapse_remit; oral; novartis
Awareness raising	Goal; goal_multiple; blog; count_donation; sclerosis_count; donation_donation; raise_goal; donation; count; energy; Month; awareness_month; march; ms_awareness; sclerosis_awareness; awareness; awareness_week; hob; ov; march_multiple

When comparing the sentiment polarity of tweets, we find that those with a lower sentiment polarity are the ones with a probability >0.6 to belong to the topics “disease modifying drugs” and “condition burden” (1.40 and 1.44 respectively, vs 1.60 for all other tweets, t-test p<0.01). Only tweets on awareness raising had a higher positive strength than the average (1.80 vs 1.60, t-test p<0.01). On the other hand, the tweets with a more negative strength were the ones dealing with condition burden and related chronic conditions (-2.53 and -2.14 respectively, vs -1.78, t-test p<0.001). Only tweets on awareness raising and disease modifying drugs had lower negative strength than the average (-1.23 and -1.61, vs -1.78, t-test p<0.05). Table 2 shows the average sentiment positive and negative sentiment values of the tweets with a probability >0.60 to belong to one of the 4 identified LDA topics, (t-tests compare the sentiment of these tweets with the tweets within the same topic with a probability <0.60).

Table 2. Average sentiment of tweets with a probability >0.60 to belong to each topic

LDA topic	Number of tweets	Positive Mean (SD)	Negative Mean (SD)
Related chronic conditions	1106	1.58 (0.6)*	-2.14 (1.3)*
Condition burden	2256	1.44 (0.6)*	-2.53 (1.3)*
Disease modifying drugs	1749	1.40 (0.6)*	-1.61 (0.7)*
Awareness raising	1171	1.80 (0.7)*	-1.23 (0.6)*
ALL TWEETS	74076	1.60 (0.8)	-1.78 (1.0)

* Students t-test, p<0.01

4. Discussion

The MS topics discussed on Twitter that were identified with LDA, and that we grouped into four main categories, are consistent with the topics discussed in a recent publication on MS Facebook groups [18]. The importance of information and awareness, treatment related issues, and other MS-related symptoms was also key in that study [18].

It is well-known that people affected with chronic conditions, such as MS, carry painful emotions in need of sharing [19], and that expressing these emotions is linked to feelings of relief and alleviation [20]. In our study we found that Tweets dealing with disease-modifying drugs, condition burden, and related chronic conditions had a significant lower positive sentiment than the average of Tweets on MS; tweets on condition burden and related chronic conditions were the most negative ones. These could represent the topics with more emotional burden for those affected with MS, and therefore the topics for which they should receive greater social support. This is in line with other literature on reported feelings of pwMS[5].

Strengths and limitations: Our study has several limitations. We extracted tweets using the standard Twitter API, that did not index all tweets published in the considered dates, and therefore, the data extraction might not be representative, and should be considered as a random sample of tweets on MS. Relevant content may not have been included due to our search strategy. Additional research could consider including other keywords related to MS, expand the search by including other languages, include other social media channels, analyse emojis and metadata such as users’ profiles. We used SentiStrength software to conduct the sentiment analysis of the collected tweets on MS. This software has not yet been validated for use in the health domain. However, it was developed using posts on Myspace and shows a good performance with informal text, such the ones that can be found on Twitter.

Conclusions: The use of tools to identify main discussed topics on social media, and to analyse the sentiment of these topics increases the knowledge of the themes that could be representing the bigger burden for people with MS. This knowledge can help to improve support and therapeutic approaches addressed to people with multiple sclerosis.

Automatic Interpretation of Laboratory Tests and Its Influence on Follow-up

Georgy KOPANITSA^{a, 1}

^aITMO University, Saint Petersburg, Russia

Abstract. Failing to follow up on the abnormal test results can cause serious health problems to patients. We conducted a retrospective medical record review of 3200 randomly selected patients aged 18 to 76 in 14 state clinics and two private laboratory services querying the common regional patient registry. One patient could be included (1 clinical case) in the study only once. We invited patients to take part in the interviews to gain a deeper understanding of the motives to follow up or not after receiving a recommendation and explanation of the role of the automatically generated interpretation in this decision. A qualitative study of the patients' motivation was performed with a group of 689 patients. All the patients who received their interpretations showed a much higher follow-up rate (68% average) than the patients who did not receive interpretations (49 % average). The results of our research demonstrated that there is a significant impact on the patients' decision to follow up on the tests. Patients consider time factor as an important advantage of the computer interpretations and are willing to get automatic interpretations if they can receive it faster than the ones from their doctor (question 4: median = 3 out of 7). Discussing the reasons behind the decision to follow up, the patients do trust the computerized clinical decision support systems (question 5: median = 5 out of 7), however, they prefer to receive interpretations and recommendations from doctors (question 3: median = 7).

Keywords. laboratory test, interpretations, decision support systems, follow-up

1. Introduction

Today, the use of computerized clinical decision support systems (CDSS) is gaining its traction in helping patients in various clinical situations [9; 19]. Such systems can produce patient-specific reminders, interpretations, and recommendations motivating a more appropriate delivery of care [10; 14]. For example, such systems are used to interpret laboratory test results [16], alert about vital signs being outside of a reference interval [11], support in dietary questions [5; 20], and many other critical issues. The effect of CDSSs on laboratory test ordering was assessed in several systematic reviews [6; 13; 15]. These reviews determined that, when integrated into clinical workflow, CDSSs have a positive influence on the process of test ordering by the doctors. However, when the decision to run a diagnostic test or to follow up on a test is switched from a doctor to a patient, the effect of a CDSS can be very strong. Direct access of patients to the test results can lead to the patients becoming better-informed [4], more engaged [8], and able to manage their care more efficiently [21]. Another potential benefit is improving patient safety. Casalino et al. discovered that 8–26% of abnormal test results are not followed up in a timely way

¹ Corresponding Author, Georgy Kopanitsa, Birzhevaya liniya 4, Saint-Petersburg, Russia, georgy.kopanitsa@gmail.com.

[3]. Pillemer et al. demonstrated that access to test results is appreciated by patients and increases adherence. However, it may cause patient nervousness and increase the number of visits [12]. Direct access to the test findings may let patients pursue a proper follow-up rate. A major concern expressed in [18] is that direct access can cause excessive patient nervousness because they can face difficulties interpreting the results. Interpretations given by a CDSS can support patients as they proved to deliver correct interpretations, provide great user experience, and are generally accepted by the patients [16]. A good and timely provided interpretation of the laboratory tests results given to patients by a CDSS, especially in the situation when a patient does not visit a doctor after the test is done can help to decide how to proceed with the diagnosis without support from a healthcare professional. The objective of the research is to study how patients perceive the interpretations of the laboratory tests automatically generated by a clinical decision support system in comparison with the interpretations given by doctors and how this affects the follow-up rate.

2. Methods

A clinical decision support system provides interpretation of laboratory test results for patients [11]. The common regional patient registry with obligatory registration of all laboratory tests helps to identify all testing events for every patient, including a list of tests that the patient ordered. We conducted a retrospective medical record review of 3200 randomly selected patients aged 18 to 76 querying the common regional patient registry. One patient could be included (1 clinical case) in the study only once. We studied 4 groups of patients:

1. The patients from the first group received their test interpretations automatically generated by a clinical decision support system with a clear indication that the interpretation was done automatically by a clinical decision support system.
2. The patients from the second group received their interpretations personally from a doctor with a clear indication that the interpretation was done automatically by a clinical decision support system.
3. The patients from the third group received their interpretations from a doctor with no indication of their automated generation.
4. The patients who did not receive any recommendations, only the test results.

We selected six laboratory tests commonly done by the patients (86.4% of all laboratory tests ordered in 2018), for which a decision support system could generate interpretations. Interpretation of each test with abnormal results included a recommendation to run another specific laboratory test or to repeat the same test again depending on the conditions of the patient. Participants were randomly selected for each group, using Random Sampling method, that ensured comparability to Russian demographic distributions. The reference intervals for the patients were taken from the recommendations of the Ministry of Health of the Russian Federation. We considered test results to be abnormal only if they were at least 20% outside of the reference range because it indicated a danger or potential risk for the patient's well-being over time.

A follow-up rate was calculated as a ratio of the number of patients who referred to a laboratory service for a follow-up investigation after receiving a recommendation within two weeks after the first test with abnormal test results had been completed and the interpretation was delivered to the patient. We calculated only the follow-up rate for the patients that had a recommendation to run additional laboratory tests. We invited patients

from groups 1 and 2 to take part in interviews to gain a deeper understanding of the motives to follow up or not after receiving a recommendation and the role of the automatically generated interpretation in this decision. The patients were invited by email and personal telephone calls. Patients were eligible for the study if they were 18 years and older and received a laboratory test interpretation during the previous months. We invited all the patients (1600) from groups 1 and 2 to participate in the interviews, 836 of them accepted the invitations: 421 from group 1 and 415 from group 2. From the patients who agreed, we formed a study group to represent the initial study population in terms of gender and age. Based on these constraints, we formed a group of 689 patients to run the study. The study was performed using one-on-one structured interviews. We asked the patients to rate questions 2–5 based on a Likert scale from 1 (not at all) to 7 (very much) [7]. For question 1, there were two possible answers: “yes” and “no”. The interviews were done by one researcher by phone or in person. The interview agenda was developed by the project team and reviewed and accepted by the ethics committee of the regional Department of Health. Before the interview, the patients were informed about the goals of the research and received a printed declaration of anonymity and confidentiality. Every patient had signed a consent form before the interviews began. Interview agenda for the patients consisted of the following questions:

- 1. Q1: Did you notice that the recommendation was generated automatically?
- 2. Q2: Do you think the fact that the interpretations are done automatically affect your decision to follow up?
- 3. Q3: Do you think doctors will give a more precise and valid interpretation?
- 4. Q4: Would you wait to get a recommendation from a doctor rather than get an immediate interpretation from a CDSS?
- 5. Q4: Do you trust the interpretation given be a clinical decision support system?

3. Results

The demographic data of the patients were recorded from the regional patient registry and presented in Table 1.

Table 1. Demographic characteristics of the patients

Gender	Group 1		Group 2		Group 3		Group 4		Age	Total
Age	>=60	<60	>=60	<60	>=60	<60	>=60	>60		
	19.4%	80.6%	19.4%	80.6%	19.4%	80.6%	19.4%	80.6%		
Males	47.0%		46.75%		47.38%		46.38%		38.8	46.87%
	74	302	70	304	76	303	72	299		1500
Females	53.0%		53.25%		53.62%		53.62%		39.4	55.13%
	97	327	95	331	97	324	99	330		1700
Total	171	629	165	635	173	627	171	629		3200

The follow-up rates for every group of patients are shown in Table 2.

Table 2. Laboratory test follow-up rate for every group

Gender		Group 1		Group 2		Group 3		Group 4	
	Age	>60	<60	>60	<60	>60	<60	>60	<60
Males		59%	60%	73%	74%	75%	79%	48%	42%
Females		61%	61%	72%	75%	73%	80%	55%	49%
Total, age-dependent		55%	61%	72%	75%	74%	80%	49.7%	46%
Total		58%		74%		78%		49%	

Average follow-up 68%
with interpretations

Patients’ attitude to the automatic test interpretations is presented in the table 3.

Table 3. Patients’ attitude to the automatic test interpretations

Question	Group 1		Group 2		Total	
	Mean	Median	Mean	Median	Mean	Median
Q1	3.4	4	3.1	3	3.3	3
Q2	6.8	7	6.1	7	6.2	7
Q3	3.1	4	3.4	3	3.3	3
Q4	5.9	5	5.7	5	6.8	5

4. Discussion and conclusion

Patients are generally willing to have access to their test results [16], so the automatically generated interpretation, especially in the case when a patient is not visiting a doctor, can enhance their experience and increase follow-up rates. Callen et al. in their systematic review revealed that 6.8–62% of laboratory tests were not followed up by patients [2; 17]. Utilization of clinical decision support systems for test interpretations can assist in overcoming the problem of failures to inform patients of abnormal outpatient findings, which is a common case now according to Casalino et al. with up to 26.2% of abnormal results not delivered to patients [3]. Automatic delivery of test result interpretations can potentially decrease the number of uninformed patients. The results of our research demonstrate that there is a significant impact on the patients’ decision to follow up on the tests. Promotion of laboratory test result notifications with detailed interpretations still demands communication effort and improvement of the algorithms to increase the reliability and trust to the patient-facing clinical decision support systems.

Abstract. People use language to express their thoughts and feelings, unveiling important aspects of their psychological traits and social interactions. Although there are several studies describing methodologies to create a collection of words in English related to depression and other conditions, in most of them the selection of words is not clinical or expert based. The objective of this study is twofold: firstly, to introduce a comprehensive collection of Spanish words commonly used by patients suffering from depression, which will be available as a free open source for research purposes (GitHub), and secondly, to study the usefulness of this collection of words in identifying social media posts that could be indicative of patients suffering from depression. The level of agreement among medical doctors to determine the best words that should be used to select tweets related to depression was low. This finding may be due to the complexity of depression and the extraordinary diversity in the way people express themselves when describing their illness. It is critical to perform a thorough analysis of the specific language used in each condition, before deciding the best words to be used for filtering the tweets in each disease. As our study shows, the words supposedly more linked to depression are very common words used in other contexts, and consequently less specific for detecting depressive users. In addition, grammatical gender forms should be considered when analysing some languages such as Spanish.

Keywords. Depression, social media, surveys and questionnaires, terminology

1. Introduction

People use words to reflect their thoughts and feelings, revealing a huge amount of information about their personality and social interactions, as well as different psychological traits [1]. Language is the medium by which mental health professionals attempt to understand human beings and mental disorders. Several studies have found that linguistic styles are indicative of depressed mood [2]. Another interesting point is that people's language is stable over time and consistent across subjects or context; consequently, it can be used as a tool to measure differences among individuals [3].

¹ Corresponding Author: E-mail: ferran.sanz@upf.edu.

Several studies used social media platforms such as Twitter to analyze psychiatric symptoms and diseases, including depression [4,5]. Although these studies describe different methodologies to create a collection of words in English related to depression and other mental disorders, in the majority of them the selection of words were not extensive or clinical and expert-based [6,7]. In addition, Spanish speaking countries, such as Spain and Mexico, are among the ten countries with most Twitter users worldwide, with more than 6 million and 7 million users, respectively [8]. As far as we know, there are no studies focused on the creation of a list of words of depression in Spanish. The selection of the best terminology and keywords in any information system, including electronic health records, bibliographic databases or social media platforms, is critical for their usefulness in management and scientific research.

The objective of this study is twofold: first, to create a comprehensive collection of Spanish words commonly used by patients suffering from depression, which will be used for streaming Twitter and that is available as a free open source for research purposes in GitHub. Second, we determine the usefulness of the different words in identifying social media posts potentially related to depression.

2. Methods

The methodological approach consisted of three phases. The first phase consisted of the review of the most common tests and rating scales for assessing depression (using their Spanish version) in order to extract terms related to the expression of the depression symptoms. The different tests and rating scales analyzed are shown in table 1. The review was carried out by a psychologist and a family physician with experience in the clinical characteristics of depression, who reached an agreement on the words representative of the language used by depressive patients. The Diagnostic and Statistical Manual of Mental Disorders, fifth edition (DSM-5) [9] was reviewed to complete the list. In this way, a list of 255 words was created.

Table 1. Tests and rating scales used for selecting words related to the expression of depression by patients (the Spanish versions were used)

Name of the tests and rating scales
Beck Depression Inventory (BDI)
Brief Symptom Inventory (BSI)
Carroll Rating Scale for Depression
Center for Epidemiologic Studies Depression Scale (CESD-R)
Clinically Useful Depression Outcome Scale (CUDOS)
Goldberg Depression and Anxiety scales (GADS)
Hamilton Rating Scale for Depression (HRSD)
Hospital Anxiety and Depression de Zigmond and Snaith (HAD)
Montgomery-Asberg depression rating scales (MADRS)
The Patient Health Questionnaire (PHQ-9)
Zung Self-Rating Depression Scale (SDS)

In the second phase, a questionnaire was created including the aforementioned list of words. The questionnaire was sent in December 2017 via email to 50 psychiatrists from the Institute of Neuropsychiatry and Addiction (INAD) of Parc Salut Mar in Barcelona and 5 family physicians from the Spanish National Health Service. The email included the purpose of the questionnaire, the guidelines for its completion and an Excel file with the words selected. A second email was sent as a reminder in February 2018. The objective of this questionnaire was to obtain a score that represented how well these

words are related to depression, as described by patients explaining their symptoms in clinical settings. The score of a word was obtained by adding the scores provided by each rater using a Likert scale (1. never, 2. rarely, 3. occasionally, 4. frequently and 5. very frequently). Since 20 raters participated in the scoring process, the maximum value of the score was 100 points. The list of 255 words and their scores are available at GitHub for research purposes: <https://github.com/angelaleism/WordsDepression>.

Finally, the third phase involved streaming of tweets that included at least one of the 375 words (the list of 255 words plus their different plural and gender forms), which was carried using the Twitter Application Programming Interface (API) [10]. The streaming was set up between June and September 2018 obtaining 8,832,256 tweets. In order to compare the usefulness of the words to detect tweets with signs of depression, two sets of 500 tweets were randomly selected after retweets removal. One of the sets was created by including five subsets of 100 tweets, each one composed by tweets that included one of the five most highly scored words, and the second 500-tweet set included low scored words. The 1,000 tweets were manually reviewed by two experts to determine whether they were potentially indicative of depression or not. The R programming language was used for the statistical analyses.

3. Results

The questionnaire was answered by 30% of psychiatrists (15/50) and all the family physicians (5/5; 100%). The respondents were 13 women and 7 men. All the respondents rated the complete list of 255 words. The mean and SD of the scores of all the participants are shown in figure 1.

Figure 1. Distribution of the means and standard deviations (SD) of the 20 participants' scores

In order to assess the reliability of agreement among the raters, we calculated the intraclass correlation coefficients (ICCs) and the agreement among all the raters was 0.47, for the psychiatrists was 0.53 and for the family physicians was 0.37.

Based on the health professionals' scores, the 10 words in Spanish most frequently expressed by depressive patients were (the translation in English is in parenthesis): *deprimido/a* (depressed), *triste* (sad), *tristeza* (sadness), *desanimado/a* (downhearted), *depression* (depression), *depresivo/a* (depressive), *ansiedad* (anxiety), *cansado/a* (tired), *lloro* (crying), *insomnio* (insomnia). The 10 less frequent words were: *autocrítico* (self-criticism), *ingrato/a* (ungrateful), *miserio/a* (vile), *languidez* (languid), *mutilado/a* (disabled), *apetencia* (hunger), *sombrio/a* (gloomy), *achacoso/a* (sickly), *desdeñado/a* (disdained), *lasitud* (weariness). It is necessary to take into account that in the translation

of these words into English there are some nuances that may be missing. There are some words that are more frequent in its feminine form on Twitter such as anxious, distrustful, distressed, insecure or shy and more frequent in masculine such as loser, solitary, incompetent or defeated.

Regarding the analysis of the tweets, table 2 shows the number of tweets that included the studied words, as well as the scores assigned to these words by the health professionals and the ranking of the words on the basis of the scores. In addition, the table shows the proportion of tweets for each word that were potentially indicative of depression when manually reviewed by an expert.

Table 2. Frequencies of words in the 8,832,256 tweets analysed, scores and proportion of depressive tweets

Word	Number of tweets	Score (Rank)	% depressive tweets
Deprimido/a	63,019	97 (1)	12%
Triste	56,776	97 (2)	5%
Tristeza	54,789	96 (3)	10%
Desanimado/a	24,079	94 (4)	23%
Depresión	51,408	92 (5)	12%
Infelicidad	12,116	63 (110)	4%
Suicida	42,615	57 (127)	1%
Vencido/a	43,020	52 (162)	3%
Melancolía	22,896	43 (194)	9%
Desdichado/a	4,663	41 (203)	9%

4. Discussion and conclusions

The diagnosis of depression is a complex process because of the heterogeneous nature of this disease, the lack of biological markers, the different symptoms among individuals and the diverse ways in which patients express those symptoms.

In relation with the scores assigned by the health professionals that participated in the survey, there was more agreement among the psychiatrists than among the family physicians. These results may be consistent with the fact that the psychiatrists deal with more patients with depressive disorders, and therefore, they are more familiar with the language used by patients with depression. As a result, the agreement between psychiatrists and family doctors is low. This finding may be due to the extraordinary diversity in the way people express themselves when describing their illness, the complexity of depression [9], how health professionals interpret these words for making a diagnosis and their clinical experience. For this reason, it is critical to perform a thorough analysis of the specific language used in each condition, before deciding the most suitable words to be used for filtering the tweets in each disease [2]. As our study shows, the words supposedly more linked to depression are very common words used in other contexts on Twitter, and consequently less specific for detecting depressive people (e.g. *triste/sad*). On the other hand, words less frequently mentioned on Twitter can have more weight to link them to depression or suicide tendency (e.g. *desanimado/downhearted*). The gender of words should be always considered when analyzing some languages that have grammatical gender forms such as Spanish.

Nevertheless, the analysis of words related to depression also require us to consider other aspects such as the linguistic features (i.e. the different use of personal pronouns, the number of negative words and the expressions associated to the basic emotions) and the behavioral patterns (i.e. the distribution of tweets over time and the number of characters or hashtags per tweet) [5]. However, the extensive list of words provided in

this study can be used as a basis for developing new studies and strategies for the analysis of depression on Twitter in Spanish. Patients can be monitored, introducing new opportunities for studying depression and providing additional health services.

This study presents some limitations. On the one hand, the tweets can be considered an indirect and inaccurate way of detecting users suffering from depressive disorders and it is not possible to verify whether the diagnosis is genuine or not. On the other hand, although the list of words was carefully developed, there may be more expressions or words not included in the list.

Design of the CAPABLE Health Empowerment Tool: Citizens' Needs and Expectations

Astri Letnes JANSON ^{a,1}, Anne MOEN ^b and Kristin Skeide FUGLERUD ^c

^a *Division of Diagnostics and Technology, Akershus University Hospital, Norway*

^b *Institute of Health and Society, University of Oslo, Norway*

^c *Department of Applied Research in Information Technology, Norwegian Computing Center, Norway*

Abstract. It is important but difficult for citizens to gain a proper overview of their health-related information. The CAPABLE project aims to create a digital tool that enable citizens to actively utilize their clinical and personal health information to manage medication, improve nutrition, and facilitate health services coordination. 57 participants have participated in various user-centered co-creation activities. A key finding of citizen's needs and expectations is that citizens are positive about such a tool provided it is easy to use and requires minimal work. Especially, opportunities to collect and utilize already existing digital health information, having access to personalized and relevant checklists and personalized resources, and be able to share health information with health personnel and others according to their own trust and privacy preferences. Involving other stakeholders to ensure integration with other systems is of principal importance to fulfil citizens' expectations of integration and automatization.

Keywords. User-centered design, inclusive design, mHealth, automatization, personalization, privacy, medication management, interoperability

1. Introduction

Today, citizens can access subsets of their health information through dedicated, secure patient portals [1], but content can be fragmented and access unequal [2], or requiring users to manually enter information into the apps of their choice [3]. Apps are usually targeting one specific condition, e.g., diabetes [4], heart failure [5] or cystic fibrosis [6] to mention a few. Over time, most people experience many health issues leading to health encounters, many of which produce information and knowledge that may be of relevance and importance for self-management and the best possible follow-up of treatments. The result is that citizens ends up managing a mix of paper documents, digital snippets of information exchanges or data in incompatible formats, supplemented with ad-hoc strategies for interpretation and management. The extent of health information exchange varies considerably, and is only partly achieved in some countries [7]. For citizens, there is currently no simple way to collect, curate or complement nor control health information from multiple institutions, services and systems, making it quite challenging to retain a good overview and understanding of its implications.

¹ Corresponding Author, Astri Letnes Janson, E-mail: astri.letnes.janson@ahus.no

We anticipate that easy access to and overview of all health-related information will contribute to increased empowerment and improved digital health literacy, which in turn can contribute positively to health status [6]. In our ongoing project, CAPABLE, we aim to support citizens' ability to manage their health and participate in health-related decisions. We are creating a mobile tool to enable citizens to actively utilize their clinical and personal health information to manage medication, improve nutrition, and facilitate health services coordination. To counteract current inequality in health services provision [8], we emphasize and pay special attention to the needs of vulnerable groups, people with disabilities, complex and or chronic conditions, and those with low health literacy. The research focus for the user-centered design process we report from was: what are the citizens' needs, values and the social context for developing the CAPABLE tool? What are the expectations of citizens for such a tool?

2. Method

The development of the CAPABLE tool is based on an inclusive user-centered design approach [9], emphasizing user involvement from the very beginning and throughout the full development and deployment cycle. Involving users in the design process contributes to increased applicability, accessibility, acceptance and adoption of the designed solution. It is considered especially efficient and influential in the early stages of the development process since the costs of making changes increases as the development continues [10]. We follow an interpretive research approach and utilize different user-centered methods. The variety and flexibility of methods allowed us to further investigate certain issues and questions, helping to clarify and identify recurring themes and topics. 57 citizens have participated in two focus groups (n=13), five personas workshops (n=15), a design workshop with five groups (n=24), a pluralistic usability walkthrough (n=4), and a paper prototype user testing (n=1). Municipalities affiliated with the project (n=3) recruited participants through existing municipal councils (elderly, disability, youth), and non- governmental disability and health organizations (n=3) recruited via their members. Participants represent citizens, from adolescence to elderly, with and without disabilities, with varying degrees of health problems, digital health literacy, and in different stages of life: pupils, workers, next of kin and retirees. We conducted a thematic analysis based on detailed field notes from all the activities.

3. Results

The analysis showed a wide range of expectations toward the CAPABLE tool – both affirming and contradictory to each other, ranging in level of detail and developmental implications. An overall, very common expectation was for the CAPABLE tool to require only small amounts of work to utilize it since many citizens experienced that creating an overview of their health information could be labor-intensive.

Providing citizens with a tool that requires them to register all their health information comes with little value, according to the participants in our research. They expected to be able to utilize the information that they are aware of already exists digitally. Presupposing imported digital health information, citizens expressed a willingness and eagerness to log additional, relevant health parameters related to their health challenges to gain knowledge and overview. In general, citizens are well aware

of the national summary care record “Kjernejournal” containing information from the last 3 years [1]. When they see themselves as healthy or have few or straightforward health issues, they find information about themselves in “Kjernejournal” as sufficient, but if conditions are more complex, they told that information could be incomplete or missing, requiring them to recall incidents from years or decades ago when asked.

Citizens anticipated that the CAPABLE tool could help them to manage experiences, questions and information before and after consultations with health personnel. To keep documentation to a minimum, citizens anticipate that checklists relevant to diagnosis, conditions or medicines could be useful. They pointed to examples of resources and information from the public health authorities or NGOs. However, CAPABLE tool should facilitate modifications in the resources it to their specific needs, according to their experiences and knowledge.

To support their memory in relevant situations, our participants would like to store health information in a secure place, where they can access it when they need to. At the same time, participating citizens were conscious of how their personal health data needs to be accessible for them, but not for their community. If functionality exists, they want to share their information with people of their own choice. The attractiveness of sharing relevant information, and decide how much information to share, for which treatment purposes and period, was high and seen as a feature for personal control.

4. Discussion

Citizens’ expect to utilize their health information with as much automation as possible comes with three main implications for design, discussed in the following.

4.1. Collecting Already Existing Digital Information

Our findings confirm previous research, which consistently find that ease of use, usability, accessibility and readability are key factors for successful adoption and use of eHealth systems [3,11-13]. Our participants go even further by emphasizing the need for and attractiveness of integration and utilization of existing digital health information. To collect existing digital health data, as we propose for the CAPABLE tool, the citizen could ask for access to personal health information from electronic sources, and save a copy of their health information for personal use, annotation, complementation, or even sharing personal health data at the person’s discretion. This approach complements established communication lines and should maintain data integrity in the source. CAPABLE build extensively on HL7 FHIR[®] resources to foster interoperability, the international leading interoperability standard, also recommended by the Norwegian Directorate for eHealth [14]. Above all, the CAPABLE tool will give the citizens an opportunity to maintain personal health information in one system, which was also a principle finding in Floch et al. [6].

4.2. Curating Personal Health Information

Personalization can contribute to making the application relevant and reduce the amount of work for each user. Kwon & Kim [15] differentiate between two types of personalization: *implicit*, based on previously collected consumer data, or *explicit* where

the consumer proactively specifies elements. In the CAPABLE tool, using an implicit approach could be possible as a starting, focal point of reference. Assumptions of health conditions can be delineated from a medication classification system, e.g. if a citizen take Carbamazepine, epilepsy is quite likely. However, the citizen might use the same drug for neuropathic pain or bipolar disorder. Moreover, the citizen may need information for conditions that cannot be deduced from the medication list. Therefore, explicit personalization would be a better strategy. As discussed by Li [16], incorrect information makes people more likely to interpret content as non-personalized, meaning that efforts to make content personalized in the CAPABLE tool can be futile. To balance these trade-offs, we propose a procedure where the citizens explicitly are asked to confirm deductions about health conditions. Further, we propose functionality where the citizens can select between predefined checklists and texts, and then add text alternatives that they miss to curate or adjust information to be meaningful for them.

4.3. Controlling Health Information

“Privacy by design” is important to comply with a legal perspective, but also paramount to the citizens’ maintained trust and willingness to use the CAPABLE tool. Recent research has found that many mHealth apps run the risk of jeopardizing the privacy of its users [17] because they do not conform to the General Data Protection Regulation (GDPR). CAPABLE needs to provide citizens with an easy and flexible way to control and share their information, while at the same time avoid unintended and unforeseen incidents. For sharing information from CAPABLE with health personnel, we plan to use SMART on FHIR to integrate CAPABLE with other health information systems if the citizen chooses to do so. This is well-aligned with The Norwegian Directorate of eHealth advice for our setting – that SMART on FHIR based on HL7 profiles is the most promising framework for application integration in EHR’s [14].

4.4. Limitations

Although this research has involved a relatively large number of participants, the current emphasis has been on the users of health services and their representatives. There is a need for further work to integrate this with the needs and expectations of other types of stakeholders. In addition, the views reported here reflect those who were willing to take part in this research project. People who were not interested or not able to participate may potentially have different viewpoints. A strength of the study is the combination of methods and the involvement of a wide diversity of citizens.

5. Conclusion

User involvement from citizen stakeholder assessment shows that it is of paramount importance to create and offer novel functionality going beyond “yet another registration tool”. Providing novel opportunities to collect and actively use digital personal health information to minimize text entry, be able to curate and annotate to meet personal needs and relevance, and ensure interoperability in privacy preserving manners could foster innovation that really empower the citizen. This user centered design approach has

informed the first step in designing the CAPABLE prototype. Based on the experiences, we will create a first prototype, piloting with approximately 50 additional users. Finally, we will carry out a large-scale feasibility trial with a proof of concept version of CAPABLE. The main challenge ahead is involving other stakeholders to meet the needs and expectations articulated from citizens.

Designing a Patient-Centered Notification System into a PHR

Mariana SIMÓN¹, Giuliana COLUSSI^a, Janine SOMMER^a, Lucila BRUCHANSKI^a,
Fernando PLAZZOTTA^a

^a *Health Informatics Department, Hospital Italiano de Buenos Aires, Argentina.*

Abstract. Personal health records could help patients overcome the anxiety related to gaps on health related information. The objective of this research was to explore what type of information was perceived by patients as useful to receive as a notification on their PHR as a framework for the design of a patient-centered notification system. We applied a qualitative approach followed by usability tests. From interviews to patients, we obtained main categories of notifications to include according to its perceived usefulness while, from iterative usability tests, we obtained a final version of prototypes developed according to patient-interface interaction experiences. This research helped us to understand patients needs and behavior to design an efficient notification system and also represents the first step for the development of clinical decision support systems for patients into the PHR with the potential to improve clinical outcomes and healthcare delivery.

Keywords. Personal Health Records, Software Design, Patient preferences

1. Introduction

At present, patients are increasingly demanding information and effective communication in order to understand the background in which healthcare is taking place [1, 2]. In this context, personal health records (PHR) are tools developed to meet these needs [1,3], helping patients to overcome the anxiety related to gaps on health information [4]. Besides, PHR contributes to the interaction of patients and families with healthcare systems, facilitating a shared decision-making process and empowerment [5, 6].

As highlighted by Johnson et. al. [7], patients usually appreciate receiving test results notifications at the appropriate time, the availability of a direct communication channel with providers, and any tool that could facilitate healthcare management. Delays related to these needs might lead to increased anxiety generated by lack of information.

The objective of this research is to explore what type of information is perceived by patients as useful to receive as a notification or reminder on their PHR. The latter, as a framework for the design of a notification system applying user-centered design techniques, to ensure information availability at the appropriate time.

2. Methods

Hospital Italiano de Buenos Aires (HIBA) is an academic non-profit tertiary level organization that covers all health specialities at different levels of the care system. Since 1998, HIBA has his own health information system (in-house) [8]. An integrated PHR is available since 2007. Its main functionalities include: appointment scheduling, test results visualization, patient-physician secure messaging, management of prescribed medication, and different modalities of teleconsultation. At present, our PHR has approximately 400,000 registered users [9].

We conducted a mixed-methods research divided into 2 stages. On the first stage, we performed semi-structured individual interviews with patients to explore what type of information they found useful to receive as a notification or reminder into their PHR, as well as the preferred means to receive it. Once the data had been collected, we defined notifications categories determining the system functionalities that would support them and finally, we designed prototypes of the different interfaces.

At the second stage we applied a user-centered interaction approach to adjust prototypes design and usability. This approach gave as a clear input on how patients used the system. The interaction of users with prototypes was suitable to detect usability problems. Test participants were asked to read aloud 4 tasks related to notification functionalities and tried to solve them. At the same time, they were requested to describe the actions they were performing, expressing their thoughts as regards the interaction with interfaces. These tests included 3 participants: the user, the facilitator, and the observer.

Both, interviews and usability tests, were performed on a convenience sample of adult outpatients on different hospital waiting areas and dates. Both were recorded previous oral informed consent. The data was kept anonymous, protecting confidentiality of participants. In what concerns to data-analysis, we proceeded to analyze the previously recorded audios and categorize the information in domains according to the main findings. Data collection and data analysis were initiated simultaneously. The analytic process was performed through codification and categorization of the information, based on a process of constant comparison. The categories were defined taking into account both the research main questions and the findings that emerged from the interviews [10].

To analyze usability tests, we classified users' problems to fulfill the given tasks using a severity 3 point scale (critical, serious and minor), and we complemented this information with participants' suggestions.

3. Results

15 interviews were conducted on patients (table 1). 80% were female and age range was from 31 to 78 years old. 100% of participants were PHR users.

Table 1 - Patients characteristics

	n: 15
Female	12 (80%)
Age	
31-50	4 (26,7%)
51-70	9 (60%)
+70	2 (13,3%)
PHR users	15 (100%)

When participants were asked about those subjects/information they considered as useful to be notified of, 5 main categories emerged:

3.1 Appointment scheduling management

Patients explained that they found suitable to be notified about their closest medical appointments and any changes on them in advance. They considered this remainder will facilitate their own time management according to health visits.

3.2 Medication management

Interviewees considered as valuable to receive notifications whenever they need to request their physician for a prescription update before it expires. Besides they expressed the need of a tracking system, with notifications, for home delivery of medication.

3.3 Test results management

Participants mentioned as useful to receive notifications whenever test results were informed and available to read into the PHR. Also, they highlighted as an advantage, to be notified when a complementary study order was close to expire.

3.4 Administrative processes

Users expressed they would appreciate being notified on different administrative procedures needed to receive medical care, such as bill payment information and help desk answers upon their requests for support, among others.

3.5 Hospital Information

Hospital news and activities were other topic in which a notification process was found useful. Another type of information included institutional changes or system

downtimes. As regards the mean by which they preferred to be notified, we didn't find consensus in favor of a unique mean of notification. Some participants chose the email, while others preferred push notifications on their mobile PHR. Besides, they suggested that the mean of notification could vary according to the type of notification.

With the information collected from patients inquiries we defined notification categories. For the notification system design, we opted for a fully customizable feature, meaning each user can configure what notification to turn on or off, upon their preferences along with the preferred mean to receive them (email, push notification or mobile PHR).

Departing from designed prototypes, we conducted 3 iterations of usability tests with final users of different ages and technological literacy levels. Each iteration cycle resulted in prototypes modifications to overcome usability problems detected until reaching a final proposal. Each testing cycle was carried out with different users. 6 patients participated in the first set of usability tests and, its results, evidenced the presence of 3 degrees of usability problems: critical, serious and minors. After some adjustments that emerged from the analysis of these results, we performed a second iteration with the participation of 8 final users. Analysis of results showed that minor problems were still present. With this in mind, we completed another set of prototype adjustments that were tested, in a third iteration, with 8 patients. After this cycle no usability problems were detected and thus, we arrived to a final version of prototypes.

4. Discussion

Results obtained from this research allowed us to design a patient-centered notification system into our PHR. From interviews with patients, we obtained 5 main categories of notifications to include in the system according to its perceived usefulness. Besides, performing iterations of usability tests to patients, we obtained a final version of prototypes developed according to patient-interface interaction experiences.

Usability evaluation and user experience are key points for design and development of PHR functionalities [11,12,13]. In line with this fact, the results of our research, contributed to a better PHR user experience. Final versions represent an efficient design adjusted to user's needs.

The development of this functionality for the PHR, might enhance patient empowerment by displaying suitable information in time, optimizing the management of health-related aspects and decision making. A notification system gives patients the option to choose what to receive and when, acting according to the delivered information. PHRs could send notifications and reminders and contribute to a better healthcare without generating alerts fatigue [14]. In concordance with our findings as regards preferred functionalities to be notified, the implementation of a notification system for test results avoids important results to be overlooked [15].

We also arrived to similar conclusions concerning means of notification, that is, the preferred mean depends on the type of notification [15]. Furthermore, evidence suggests that message or notification systems to patients can improve outcomes such as infant vaccination coverage by sending reminders to patients [16] and increase smoking cessation rates [17]. This research also represents the first step for future research for the development of clinical decision support systems for patients into the

PHR. These tools might contribute to the shared-decision model with the potential to improve clinical outcomes and healthcare delivery.

Developing an Intervention to Implement Electronic Patient-Reported Outcomes in Renal Services in the UK

Sabine N VAN DER VEER^{a,1}, Angelo ERCIA^a, Fergus J CASKEY^b, Ken FARRINGTON^c, Francine JURY^a, Michael REES^d, Tim Whitlock^e and Sarah KNOWLES^f

^eUK Renal Registry, The Renal Association, Bristol, UK

^fHealth Sciences, University of York, UK

Abstract. Routinely collecting and using electronic patient-reported outcome (ePRO) data in clinical practice can improve patients' experience and outcomes, but implementing this at scale has proved challenging. As part of the *Optimising routine collection of electronic patient-reported outcomes* (OPT-ePRO) study, we therefore developed an intervention that aimed to facilitate the implementation of ePROs. We are conducting OPT-ePRO in the context of secondary care for people with chronic kidney disease in the UK, with three renal units participating as our study sites. Intervention design was guided by Normalisation Process Theory, and informed by published literature and qualitative research. The intervention consisted of a national infrastructure to securely collect, transfer and display ePRO data, complemented with materials and procedures to support kidney patients and renal unit staff with embedding ePROs in usual care pathways. The next step will be to bring the OPT-ePRO intervention into practice and iteratively refine it.

Keywords. eHealth; Patient-generated health data; Symptom assessment

1. Introduction

Electronic patient-reported outcome (ePRO) data is digitally collected information that reflects the personal impact of illness and treatment as assessed by patients, such as information on symptom burden or quality of life. Studies have shown that routinely collecting and using ePRO data as part of clinical care can improve patients' experiences and outcomes [1], while also informing audits and commissioning of services. The challenge now is to implement ePROs more widely in order to harness these potential benefits.

Despite extensive knowledge on how to successfully implement ePROs [2,3], national initiatives have struggled with low response rates [4,5]. One issue is that patient and staff engagement in the implementation varies widely between groups and

¹Corresponding Author, Sabine N van der Veer, E-mail: sabine.vanderveer@manchester.ac.uk

facilities, and is often limited [4,5]. This may be explained by insufficient support for embedding collection and use of ePROs into usual care pathways. Therefore, we developed an intervention aimed at facilitating implementation of ePROs into clinical practice, with UK renal services as the exemplar context. This formed the first phase of the *Optimising engagement of routine collection of electronic patient-reported outcomes* (OPT-ePRO).

2. Methods

2.1. Theoretical framework

We used Normalisation Process Theory (NPT) as the theoretical framework to guide development of the OPT-ePRO intervention [6]. NPT has been widely used to plan implementations of eHealth interventions in clinical practice [7] and consists of four constructs: coherence (e.g. do users have a shared view of the intervention's purpose); cognitive participation (e.g. do users understand and agree on who will deliver the intervention); collective action (e.g. do existing resources and systems allow the intervention to 'fit'); and reflexive monitoring (e.g. how do users appraise the intervention's value).

2.2. Study setting

Secondary care for people with chronic kidney disease in the UK is provided by over 70 main renal units; three of these acted as our study sites. We selected renal units as our study setting because they are more digitally mature than many other parts of the National Health Service. All renal units have an electronic patient record (EPR) system connected to a national infrastructure. Currently, this infrastructure—commissioned by the Renal Association—enables digital clinical data from renal units' EPRs to flow into a national repository to facilitate: audit by the UK Renal Registry; research; and patients' self-management via a patient portal (<https://www.patientview.org/>) (see Figure 1). As part of the OPT-ePRO intervention, we aimed to make this infrastructure bidirectional: with ePRO data—in our case: symptom burden and EQ-5D (i.e. quality of life) scores—flowing from the portal through the repository into renal units' EPRs.

2.3. Approach to intervention development

To develop the intervention, we used literature reviews [2,3] and frameworks [8,9] on implementing ePROs in general, complemented with context-specific qualitative data and stakeholder codesign (see below). We recruited participants from our study sites:

- Non-participant observations of workflows: we observed three 4-hour outpatient clinics (total: 12 hours) and eight in-centre haemodialysis sessions of nearly five hours each (total: 39 hours) to gain insight into existing routines and to identify opportunities for collecting and discussing ePROs. We used a data collection template to gather field notes on e.g. patient time and activities; staff presence and activities; and on how patient data was recorded, reviewed and discussed;
- Observations of clinic consultations: to understand if and how symptoms and quality of life were discussed, we audiorecorded and transcribed 11 routine clinic visits (177 minutes in total) in haemodialysis and outpatient settings;

- Participatory co-design workshops; we conducted three workshops with patients and caregivers (total n=25) and two with staff (n=13) to review designs and prototypes of intervention elements; identify potential implementation barriers; and to co-create solutions to overcome these through collaborative synthesis. Each workshop took approximately three hours.

Guided by our theoretical framework, we thematically analysed field notes, consultation transcripts and workshop materials. Using the constant comparative method [10] we synthesised results across sites, settings and data sources. We described intervention elements in line with relevant reporting guidance [11], while mapping them to NPT constructs. To deliver the IT-related intervention elements, we worked closely with study sites’ IT departments and the patient portal supplier. We provided them with technical and functional requirements (developed with input from end users and the Renal Association), as well as an end-to-end test plan and data.

The UK Health Research Authority’s Research Ethics Service, North West - Greater Manchester West Research Ethics Committee approved the study (ID 245870).

3. Results

The extended national infrastructure as outlined in Figure 1 encompassed all IT elements of our OPT-ePRO intervention. It enabled patients to enter ePRO data at home or in clinic via the existing patient portal, which they could access on any PC or mobile device. Many patients already had access to the portal, but only some were actively using it. Before each clinic consultation, staff would invite a patient to enter their ePRO data. Within 2-3 minutes, results were sent to the national data repository, and then pushed into the renal unit’s EPR system for clinical staff to review and discuss with the patient. An overview screen in the EPR displayed current and previous ePRO results in tabular format, with colour coding linked to symptom severity. When

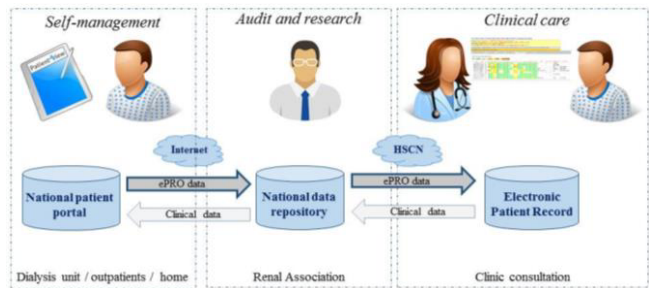

Figure 1 National infrastructure for capturing, storing, transferring and displaying ePRO data for people with kidney disease in the UK. HSCN refers to the NHS’ secure Health and Social Care Network

discussing results with patients, clinicians could generate pop-up screens to graphically display scores for individual ePRO items. There was a review functionality in the portal for patients to access their own ePRO results.

We identified relevant intervention components relating to values and roles, presented in Table 1 under the NPT constructs of coherence and cognitive participation. Components relating to service organisation and delivery are presented under collective action. We will explore reflexive monitoring –the process by which users adapt to and collectively assess the impact of the intervention—in future work evaluating the intervention in practice. Materials and procedures for each element left room for individual sites to organise the ePRO implementation in a way that fitted their local

context. All staff materials were combined into a handbook that contained information on how different aspects of the ePRO implementation would work. Patient materials were mostly delivered as flyers with concise messages, handed out in clinic or included in patient letters. Local champions were involved in delivering several parts of the intervention, and were usually a nurse manager and a consultant nephrologist.

Table 1. Overview and description of OPT-ePRO intervention elements, organised by NPT construct

Element name	Materials and procedures (what)	Delivery (how, by whom, where)
<i>COHERENCE & COGNITIVE PARTICIPATION</i>

4. Discussion and conclusion

We developed a theory-informed and co-designed intervention to facilitate implementation of ePROs into UK renal services by supporting patients and staff with

embedding collection and use of this data into usual care pathways. Previous studies explored the feasibility of using tablets in renal settings to support ePRO collection locally [12,13], but our study is the first to deliver an infrastructure that is nationally scalable. In addition, we proposed a strategy to optimise use of ePROs in these settings, thereby addressing an acknowledged gap in the literature [14].

In the next phase of the OPT-ePRO study, we will evaluate the intervention in practice. When sites deploy the intervention, we will monitor for low ePRO response rates and conduct qualitative research to identify implementation barriers and to explore ways to address them. The qualitative research will also give us insight into how patients and staff understand and experience the intervention. This will inform iterative modifications of the intervention, mapped to the reflexive monitoring construct of our theoretical framework. Once all major barriers have been addressed, we expect the intervention to be suitable for deployment by other renal units, thereby enabling national implementation of ePROs in UK renal services and contributing to harnessing their potential benefits for patients and healthcare services.

Acknowledgments

The OPT-ePRO project is supported by the Health Foundation, an independent charity committed to bringing about better health and health care for people in the UK.

Development of a ePRO-Based Palliative Care Intervention for Cancer Patients: A Participatory Design Approach

Christina KARAMANIDOU^{a,1}, Christos MARAMIS^a, Kostas STAMATOPOULOS^a,
and Vassilis KOUTKIAS^a

^a*Institute of Applied Biosciences, Centre for Research and Technology Hellas, Thessaloniki, Greece*

Abstract. This paper describes a qualitative study conducted in the context of developing a novel ePRO (electronic Patient Reported Outcome) based palliative care intervention for cancer patients. The aim of the study was to elicit end-users' needs, judgements of the MyPal system and recommendations for improvement. A participatory design was chosen as the value of this approach has been well established in eHealth systems' design as well as the development of novel healthcare services. Focus groups with Chronic Lymphocytic Leukemia (CLL) patients were conducted at the Centre for Research and Technology (CERTH) in Greece using specially designed vignettes and discussion guides. Findings revealed that patients saw MyPal offering increased, direct contact with the healthcare team, freedom of physical and psychological symptom reporting as well as valid and reliable information. However, they had concerns about the appropriate use of data collected by MyPal, the efficiency of data analysis and data security adopted for sensitive personal information. The participatory design approach used has been very useful in encouraging the genuine involvement of participants, a factor which over time can empower and promote participants' long-term engagement.

Keywords. Palliative care, cancer, electronic patient reported outcome (ePRO), Participatory design, Focus Groups, eHealth

1. Introduction

There is a growing body of research demonstrating the value of participatory design in the development of novel healthcare services. In the context of palliative care, namely supportive care aiming to improve the quality of life of patients facing life-threatening illness through the assessment and treatment of psychosocial, physical and spiritual problems [1], participatory design is especially relevant. Considering that the demand for palliative care is increasing, discrepancies between care needs and care arrangements must be noted and rectified [2]. Actively involving patients in the design or development of eHealth tools [3], resources [4,5] or systems [6] for palliative care can provide a unique perspective on user acceptability, system usability as well as insight into the feasibility of the overall effort [7].

MyPal (<https://mypal-project.eu/>) is a collaborative H2020 research project, funded by the European Commission, aiming to use eHealth technologies, in order to support cancer patients and healthcare professionals (HCPs). The main goal of MyPal is to develop and clinically assess new ePRO-based interventions for the palliation of cancer patients, in order to improve their Quality of Life (QoL) [8]. One group of cancer patients targeted by MyPal includes adults suffering from specific chronic hematologic malignancies. MyPal has committed to both adopting a patient-centered approach and adapting technology in order to cater for fundamentally different profiles of patients of different age groups as well as levels of digital and health literacy. Therefore, during the MyPal intervention design and protocol development, it is imperative to take into account not only the context i.e. current clinical practice for cancer patients, their interaction with healthcare professionals, provision of palliative care etc., but also users' personal needs as they identify and express them. To this end, use case scenarios were defined for the implicated stakeholders (patients and HCPs) to better illustrate the use of MyPal's technological tools appropriately responding to user needs in realistic situations. The aim of the present study has been to elicit the needs of end-users' representatives, their judgements with regards to different aspects (i.e. functionalities, characteristics) of the MyPal system, and finally their recommendations for system improvement.

2. Method

This was a cross-sectional study employing a qualitative methodology. Qualitative data were gathered via focus group discussions [9]. Ten focus groups (4-8 participants each) were conducted with: a) adult patients with a diagnosis of either Chronic Lymphocytic Leukemia (CLL) or Myelodysplastic Syndromes (MDS), and b) HCPs working in participating hospital units. Focus groups were conducted in partner sites in Greece (n=5; Italy (n=1); Germany (n=2), and the Czech Republic (n=2). This paper presents our overall methodology and the findings from the two focus groups conducted with CLL patients at CERTH, Greece.

With respect to materials used, two versions of vignettes were prepared: one for HCPs and one for adult patients. The following vignette, prepared for CLL patients, introduces the main character, Mr. Leonard Jones and his journey of managing CLL. The scenario starts with the enrollment of a treatment naïve patient, into the study. On Day 0 he completes the entry questionnaires, signs an informed consent and receives the MyPal smartphone application as well as a smart wristband. On Day 7, Mr. Jones receives a motivational message aiming to keep him engaged to the MyPal system. Two weeks later, he receives a notification to fill in the 1st symptom questionnaire via which he reports some fatigue, also is also becoming evident through a reduction in his physical activity. On Day 18, Mr. Jones searches for information in the personalized medical information search. He finds out that symptoms like fatigue combined with swollen lymph nodes can signify CLL progression. On Day 22 he develops rash and reports it via the spontaneous reporting functionality of MyPal app. He uploads a photograph and marks all his symptoms including swollen lymph nodes on a list. As all indicators (spontaneous reporting, symptom questionnaires and wristband data) demonstrate that CLL has progressed, MyPal issues an indication to the treating physician, who contacts Mr. Jones and asks him to undergo blood tests. After verification, on Day 24, Drug D is prescribed to Mr. Jones. He checks for drug

interactions and inserts timing preferences for reminder notifications on the MyPal app. Mr. Jones continues to receive motivational messages and self-report questionnaires to complete on physical and psycho-emotional symptoms. Mr. Jones keeps experiencing diarrhea, so on Day 42 he reports it via the MyPal app and his clinician is notified. As the diarrhea persists, he develops distress, evident in his facial expressions and tone of voice. Due to the distress picked up by the smartphone sensors in conjunction with the spontaneous reporting by Mr. Jones, the clinician is alerted and calls to reassure him. A sample screenshot from the vignette under discussion is presented in Figure 1.

The discussion guides reflected the episodes of the vignettes from enrollment up until the end of the storyline. An example follows: *‘Mr. Jones starts feeling fatigue and searches for info, since he thinks this might indicate disease progression. The information that he finds via MyPal is personalized, i.e. information relevant to him as a CLL patient. How do you judge this feature? How would you feel given the opportunity to access information tailored for you as a patient with CLL? How can it be improved?’*.

Figure 1. Sample screenshot from the patient vignette.

Concerning data analysis, the framework method was employed [10] for performing thematic analysis. It is an established approach for managing and analyzing qualitative data in applied health research [11]. Ensuring uniformity of the focus group analysis in the different participating sites was a primary concern. The main reasons for choosing this method of analysis included: a) the multi-disciplinary research teams involved, b) the sample with clinical and patient representation, c) the complexity of the collected data pertaining to 4 different countries and languages, and d) the nature of the data consisting of expressed positive and negative judgements as well as concrete recommendations for MyPal system development. The collection of data in diverse cultural contexts and from multiple perspectives contributed to the richness and thickness of data. Codes were developed at a national level and these were grouped into categories at a European level. Researchers are satisfied that data saturation has been achieved per emerging category for both clinical and patient groups.

User acceptance is not only a methodologically major challenge, but also one of significant ethical importance as it aims to enhance patients' autonomy and is directed towards their beneficence [12]. MyPal is indeed tailoring the technological aspects of the intervention to the exact patient needs, rather than requiring patients to adapt themselves to the employed technology. During recruitment participants were informed about the study, gave their consent for participation, recording of the discussion and use of content for the needs of the MyPal program. The information collected did not include any personal data but rather information on the functionality of the system as well as recommendations for better use. It must be noted that in the clinical studies to

follow later in the course of this project, consent forms will be submitted with the actual protocol to the appropriate Research Ethics Committees for approval.

3. Results

Nine patients with CLL, aged 39-73, participated in the two focus groups held at CERTH, Greece. Five were males and four were females. Three participants were receiving treatment at the time of the focus group, four had received treatment in the past, while two were treatment-naïve. CLL patients expressed what they considered to be the most important advantages that the MyPal system has to offer (Table 1), but also voiced important concerns (Table 2). Participants have given recommendations which have led to amendments in the MyPal system design and MyPal intervention delivery. Indicative examples can be found in Table 3.

Table 1. Patients’ positive judgements on aspects of the MyPal system.

Themes	Explanation
Valued contact with the healthcare team	MyPal promotes direct contact with the doctor, instantly updating the medical file and, thus, expediting medical decision-making and initiating supportive treatment following the presentation of an issue the patient is concerned about.
Freedom of reporting	MyPal allows the communication of physical and psychological symptoms attributed to either the disease or its treatment through ePROS or other information difficult for patients to assess. Patients positively perceived MyPal’s capability to record on a scheduled or spontaneous basis, in a structured or unstructured way.
Validity and reliability of information	The MyPal database will relieve them from stress and put a stop to misinformation. It will be safer and much more specialized than most generic databases available on the web since many physicians will be contributing throughout the study.

Table 2. Patients’ concerns regarding aspects of the MyPal system.

Themes	Explanation
Reliability of collected data	The data generated might not provide essential or reliable information (e.g. the data on the quality of sleep might be affected by the use of sleeping aids).
Interpretation of collected data	The data gathered might not be interpreted correctly (e.g. smartphone sensors might not be able to distinguish real distress from happiness and exertion). The need to combine different sources of information, so that data is interpreted in context was stressed.
Privacy and digital safety of collected data	Patients desired transparency over issues such as who will be viewing their personal files, who these data belong to, where data will be stored, etc. Finally, concerns were voiced about safeguarding privacy, e.g. whether the system will be recording information without patient consent and/or awareness (e.g.. smartphone sensors reading facial expressions and tone of voice).

Table 3. Impact of participants’ recommendations on MyPal system design and intervention delivery.

MyPal proposal	Participants’ feedback	Amendment Decisions
MyPal will notify participants that a PRO assessment is due and accept submitted PRO reporting	Patients stressed the need for feedback after submission	The MyPal system will issue a notification to inform the participant that the information has been successfully submitted and that it will be seen by a HCP as soon as possible.
The MyPal system was designed to record spontaneous symptom reporting and scheduled symptom reporting	Patients expressed concerns that the physician will not see the information in real time or that he/she will not be available or not respond	Informed consent will state that MyPal is not an emergency service. During symptom reporting, patients will be informed that in case of emergency they should contact the hospital directly. Participating HCPs will check the system for new information every 72 hours.

4. Lessons learnt

The purpose of this study was to present the vision of the MyPal system to all implicated stakeholders. Findings from the focus groups conducted with CLL patients offered insights into patients' requirements from an eHealth system like MyPal. It was evident that, in order to support patients and their caregivers in getting the most of MyPal, it is necessary to alleviate their concerns about the appropriate use of data and the efficiency of data analysis, while also providing reassurance with high standards of data security adopted for sensitive personal information. End users' valuable contributions are already informing and shaping the MyPal design and the next cycle of iteration has already been planned for preliminary field testing. The employed participatory design approach has been very useful in that it has encouraged genuine involvement of participants, a factor which over time can empower and promote participants' long-term engagement.

Development of a Mobile Digital Manikin to Measure Pain Location and Intensity

Sabine N VAN DER VEER^{a,1}, Anna L BEUKENHORST^b, S Mustafa ALI^b, Ben JAMES^c, Pedro SILVA^c, John McBETH^b, William G DIXON^b

Abstract. Painful conditions are prevalent and substantially contribute to disability worldwide. Digital manikins are body-shaped drawings to facilitate self-reporting of pain. Some of them have been validated, but without allowing for recording of location-specific pain intensity and for use on a smartphone. This paper describes the initial development of a digital pain manikin to support self-reporting of pain location and location-specific intensity using people's own mobile device. Subsequently, we conducted reliability and usability tests with eight researchers and seven patient representatives. Test-retest reliability depended on the manikin's level of detail, but was generally high with most intraclass correlation coefficients ≥ 0.70 and all similarity coefficients ≥ 0.50 . Participants found the manikin easy to use, but suggested clearer orientation (front/back, certain body locations) and would value additional feedback and diary functions. We will address these issues in the next version of the manikin before conducting a validation study.

Keywords. Pain measurement; Patient-generated health data; mHealth

1. Introduction

Pain is one of the leading causes of disability worldwide [1]. It is a symptom of all musculoskeletal diseases, and prominent in many other conditions, such as cancer. Pain substantially affects people's quality of life and imposes a significant burden on society due to treatment costs and absence from work [2]. To optimally manage pain and understand treatment response, we need insight into how it changes over time. This requires validated instruments to capture key aspects of pain, which often vary per location, such as pain intensity.

Digital manikins are human-shaped drawings where people can shade areas to self-report the location of their pain on a computer. In contrast to their paper counterparts, digital manikins support automated (rather than manual) calculations of e.g. the extent of the affected area. Previous studies presented validated, digital pain manikins [3–5], but none of them facilitated the capture of location-specific pain intensity (i.e. different intensities for different locations within one pain report). They also required a dedicated device with a pre-defined screen size, limiting opportunities for people to use their personal devices, which in turn hampers deploying these manikins for large

¹ Corresponding Author; E-mail: sabine.vanderveer@manchester.ac.uk

mHealth studies. Manikins incorporated in pain self-management apps that are currently available in app stores (e.g. <https://www.catchmypain.com/>) are unsuitable as research tools because they have not been validated as measurement instruments. We, therefore, developed a digital pain manikin to enable people to self-report the location and location-specific intensity of their pain using any (mobile) device. This paper reports its initial development and usability testing.

2. Methods

2.1. Initial development

We developed a prototype, for Android IOS in the first instance, together with an industry partner (<https://www.umotif.com/>). The prototype design was guided by the manikin's intended purpose, published digital pain manikin studies [3–5], and input from clinicians and researchers with pain measurement expertise. The manikin was two dimensional, black, and gender-neutral with anchors for chin/back of the head and groin/buttocks; users could select a zoomed-in view on the lower arm and hand. There was a slider to indicate pain intensity before shading an area; score and colour ranged from 1 (grey; no pain) to 10 (red; severe pain). Users could erase incorrectly shared areas by selecting an intensity of 1. There was a visible grid with squares overlaying the manikin; 'active' squares were those that had been shaded with intensity >1. A mechanism for exporting a table with the coordinates and intensity scores of all active squares facilitated a pain score calculation that was not influenced by screen size.

2.2. Selecting the optimal grid

As we expected the grid's granularity to affect both user experience and the accuracy of pain drawings, we evaluated the usability and reliability of three grids with different granularities: coarse (40x80 squares); medium (80x160); and fine (100x200); we tested full body and zoomed-in arm manikins separately. We aimed to identify the grid that best balanced ease of use with drawing accuracy.

We recruited eight researchers from our professional network; five had experience with measuring pain. A sample size of eight was sufficient to detect an intraclass correlation coefficient (ICC) of 0.70 or more [6], found by previous studies [3–5]. After receiving verbal instructions and completing one practice drawing, participants completed a first test set of six drawings (i.e. one for each grid-manikin combination) on a Samsung S6 smartphone by copying an example manikin from paper (Figure 1); we randomised the order in which grids were tested. We then interviewed participants for 30 minutes to explore their views on the ease of use of each grid before asking them to complete a second set of the same six drawings (i.e. retest).

For each grid-manikin combination we evaluated the test-retest reliability of pain extent by calculating (i) the size (i.e. mean of difference) and range (i.e. limit of agreement as $\pm 1.96 \times \text{standard deviation}$) of within-participant differences between test and retest [7] for the proportion of active squares within the manikin perimeter, and (ii) the ICC [8]. For the test-retest reliability of pain location we calculated the Jaccard similarity coefficient (per [3]), which is the number of squares that were active in both test and retest divided by the number of squares that were active in either test or retest; values range from 0 to 1 (no to complete overlap in pain location). We also calculated mean completion time during the retest and synthesised interview notes per grid.

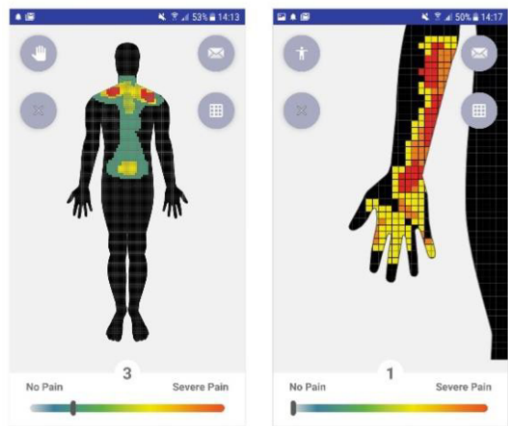

Figure 1. Screenshots of the medium grid body manikin (left panel) and arm manikin (right panel), as completed on a Samsung S6 smartphone by one of the participants

2.3. Exploring usability

We explored the general usability of the digital pain manikin, including the manikin’s ease of use; its look and feel; and suggestions for additional functionalities to improve its usefulness for pain management more widely. We collected qualitative data through the researcher interviews (see 2.2), complemented with a 3-hour workshop with seven members of a patient and public involvement (PPI) panel with personal experience of chronic pain. The workshop included individual 30-minute sessions where participants were interviewed and performed a series of tasks with the manikin using the medium grid. They then shared their experiences in a group discussion. We imported written interview and workshop notes into NVivo and analysed them thematically.

3. Results

3.1. Grid selection

Table 1 shows that for pain extent, the coarse grid had the lowest test-retest reliability for both manikins with the highest mean of difference and the lowest ICC. The medium grid performed best for the body manikin, with the lowest mean of difference and the highest ICC. The fine grid showed the best results for the arm manikin. For pain location, the test-retest overlap was comparable between grids for the body manikin. For the arm manikin, the coarse grid showed most overlap, but also the highest proportion of active squares in test and retest. Within grids, completion time varied widely between participants but generally increased with granularity.

Compared to the fine and medium grids, participants found the coarse grid easier to use but also felt it produced the least accurate pain drawings. Others reported a higher risk of unintentionally activating squares, and having to dab (rather than draw) to shade areas. In contrast, they considered the fine grid the most time-consuming, but also the most accurate method that felt most like drawing. Some participants questioned whether real pain reports would require such a fine level of detail. For the

medium grid, most participants reported similar experiences as for the fine grid, although some explicitly stated that the medium grid better balanced ease of use with drawing accuracy.

Table 1. Test-retest reliability of pain extent and location, and completion time per grid-manikin type combination

Manikin type →	Coarse grid (40x80)		Medium grid (80x160)		Fine grid (100x200)	
	Body	Arm	Body	Arm	Body	Arm
<i>Extent</i>						
Number of available squares ^{a)}	1,866	133	6,922	483	10,519	734

<i>Completion time (retest)</i>						
Mean (SD) number of seconds	64.0 (57.4)	47.5 (21.7)	72.0 (52.2)	68.2 (40.7)	82.1 (33.7)	70.1 (42.2)

Abbreviations: CI, confidence interval; ICC, intraclass correlation coefficient; SD, standard deviation
^{a)} Total number of squares in the grid that fall within the manikin perimeter
^{b)} Proportion of available squares shaded with pain intensity >1
^{c)} Difference and limit of agreement between test—retest [7] in the proportion of active squares

3.2. Usability of the manikin

All participants found completing a manikin report easy and expected basic user instructions and some practice to be sufficient for most people to use it unsupervised. Some participants made sweeping movements to activate squares, while others dabbed, especially PPI members. Dabbing was more time consuming, which may explain why some PPI members would prefer a coarser grid. Many participants ‘pinched’ in an attempt to zoom in on certain body locations, but were equally happy to use the predefined zoomed-in views. Some participants struggled to activate squares as intended, especially on the border of the manikin perimeter. The method for deactivating squares was considered acceptable, although some suggested an eraser or ‘undo’ function.

Most participants saw the manikin as male, and PPI members additionally characterised it as “elongated” and “a frog man”. Additionally, many had trouble distinguishing front from back and therefore suggested adding labels (front/back, left/right), as well as more and clearer anchors (e.g. chest, lower back). They generally liked the grid being visible, and most considered the colour scheme for pain intensity appropriate. However, some found green colours for scores of 4-5 counterintuitive and many would prefer an intensity score of ‘0’ (rather than ‘1’) to reflect ‘no pain’. No one expressed concerns with the manikin being black.

Participants suggested several additional functionalities for improving the manikin’s usefulness for pain management, including: option to record additional pain aspects (e.g. location-specific pain type (throbbing, stabbing, etc.)), pain interference with daily life); feedback of pain reports over time (e.g. heat maps); diary to record free text information alongside a manikin report (e.g. description of the pain experience); and an option to share manikin reports with your doctor to inform (tele)consultations.

4. Discussion and conclusion

We developed and tested a digital pain manikin that facilitates measuring self-reported pain location and location-specific intensity on any device. Study participants found the manikin easy to use, and it generally showed moderate to very high reliability.

A limitation of our study is that we asked participants to copy a detailed manikin example, which might be more complex than reporting a personal pain experience. They also had to do this 2×6 times instead of the usual 2×1. The increased task complexity and repetitiveness may explain why our ICCs for pain extent did not exceed the 0.90 reported by other studies [3–5]. The reliability of pain location seemed less affected by this, with Jaccard similarity coefficients in some other studies not exceeding 0.50 [3,5].

Overall, the fine grid came out as most reliable across manikins, but the usability tests suggested that it might be too difficult and time consuming to use. The next version of the manikin will, therefore, use the medium grid, as well as addressing most of the issues and suggestions this study identified, such as: providing written user instructions; improving the look and feel of the manikin; facilitating the capture of additional pain aspects, and including diary and feedback functions. Through continued collaborations with patients, clinicians, researchers and industry, we will use the new manikin version to collect digital pain reports in a range of painful conditions to (i) reassess the manikin's reliability for capturing people's personal pain experience, and (ii) develop and validate algorithms for calculating quantitative manikin scores that combine pain location, extent and intensity. Ultimately, we expect this contribute to our digital pain manikin becoming a new standard for digital pain reports in large mHealth studies, while also being suitable for supporting clinical care and self-management.

Acknowledgments This project was supported by the Centre for Epidemiology Versus Arthritis (ref 20380).

Digital Support for Self-Management in Children with Diabetes: Understanding Their Needs and Developing a Design Concept

Nicole Safavi ANDERSEN^a, Louise Hedrich HAUGAARD^a, Sissel Bøgh PEDERSEN^a, Mikkel Strange PEDERSEN^a & Ann BYGHOLM^{a,b} ¹

^a*Department of Communication and Psychology Aalborg University Denmark*

^b*Danish Centre of Health Informatics, Aalborg University Denmark*

Abstract. In this paper we present a study on the needs and requirements in a digital tool to support self-management in children and adolescents (0-18 years) with type 1 diabetes. The study was formally initiated by the Steno Diabetes Center North Jutland (SDCN), which wanted to develop a virtual universe that could support children and young people in coping with their disease. Through this study we interviewed the project manager from SDCN and the head of the family group in North Jutland. Furthermore, we observed a workshop involving health care professionals and learning specialists who were working with ideas for the virtual universe. We conducted two focus group interviews, one for children with type 1 diabetes and one for parents with diabetic children. The analysis of the data revealed very different ideas about what digital support is important for the self-management of this target group. Health care professionals focused on developing various learning materials using virtual reality or augmented reality, while the parents desired security and control and requested materials that could inform and educate people in their locale, such as school teachers, parents of their children's friends, etc. The children emphasized the importance of not being singled out and requested simple tools that could be used from their smartphones. They especially asked for tools that could help them manage their diabetes by themselves in a fast and effective way, e.g., making it easier to count carbohydrates and calculate their insulin intake. Based on the analysis, we developed suggestions for a design. The main lesson learned from this study was the importance of focusing on the *actual* users and their everyday lives in developing new tools, and not on technological possibilities.

Keywords. diabetes; app design; user research;

1. Introduction

In 2017, approximately 425 million adults (20-79 years) and more than 1,106,500 children lived with the chronic disease diabetes [1]. The most well-known types of diabetes are type 1 and type 2. Type 1 diabetes occurs when people cannot produce insulin themselves and type 2 diabetes occurs when people cannot use insulin to turn glucose into energy [1]. The study presented in this paper focuses on children diagnosed with type 1 diabetes [2].

¹ Ann Bygholm, ann@hum.aau.dk,

Diabetics have an increased risk of serious health issues and complications, including cardiovascular disease, blindness, kidney failure, and lower limb amputation [3]. It is therefore important that children and young adults learn to self-manage and take responsibility for their disease even at a young age. To help children and young adults manage their diabetes, the Steno Diabetes Center North Jutland (SDCN) wished to develop a digital concept that supports diabetic children and their families in their everyday life. When we began our cooperation with SDCN, the vision for the project was still in a very early state, but SDCN knew they wanted “something digital” and were interested in the idea of a virtual universe for the children. It was important that the digital device would support self-management and empowerment, that is, to maximize the self-care knowledge, skills, self-awareness, and sense of personal autonomy of patients and to enable them to take charge of their own care [4].

To understand the context of diabetes-related technology, we explored existing ICT apps and tools for diabetes on the market. We found several diabetes-related apps, but almost all the apps were made for monitoring diabetes. We found only one app, provided by the Danish Diabetes Association, that was developed to help children master and manage diabetes. Monitoring and mastering/managing are different types of help: monitoring focuses on keeping track of your numbers (insulin, blood glucose levels, etc.) while self-mastering also focuses on having the knowledge and competences to handle and manage the disease. The collaboration with SDCN led to a study on the needs and requirements for digital support to aid self-mastery for diabetic children, aged 10-18 years, in order to develop suggestions for a design.

2. Methods

For this study, we applied a user-centered approach [5] to understand the aims and needs of the stakeholders: the children, the parents, and the health care professionals.

We conducted an unstructured interview with the project manager from SDCN with the aim of understanding the thoughts and wishes regarding a virtual platform for children and teenagers and why this project was initiated. A few days after this interview, we participated in a SDCN workshop to inspire innovation in digital health for children and teenagers with type 1 diabetes. Doctors and nurses from Aalborg University Hospital worked with two digital learning specialists from a company called CadPeople and the project manager from SDCN. While observing this workshop, we conducted an unstructured non-participatory observation and took fieldnotes. After collecting data from health personnel and experts, we wanted to obtain the users' perspective. Therefore, we had a conversation with the chairman of the Danish Diabetes Association of Northern Jutland. Through our contact with the chairman, we arranged two separate focus-groups, one with 8 children, aged 9-13 years, and another with 7 parents. We prepared an interview guide for the children with questions that allowed us to focus on their experiences and feelings about being diagnosed with diabetes and dealing with the disease. We asked the parents questions about parenting a child with diabetes. As expected, the parents were able to reflect upon the questions, whereas the children needed help. Therefore, we chose to include the generative techniques inspired by Sanders and Stappers [6]. We used pictures in the form of different social activities to provoke reflection and help the participants to recall memories, make interpretations, explain feelings, and imagine future experiences.

Data from the interviews, observations, and focus groups were transcribed in order to for us code it and draw out the relevant knowledge from the study. The coding process was approached with an open mind; as a framework we followed Braun and Clark's six-step thematic coding [7]. This led to the identification of important themes that are presented in the findings below.

3. Findings

The identified themes represent the different issues and challenges that the children and their parents encounter on a daily basis, including "Practical challenges with diabetes," "Challenges when educating the network," "Lack of knowledge about the illness," "The balance between independence and childhood," and "Overprotective parents". We condensed the themes further and ended up with three main concerns that should be addressed in a digital tool that could support self-management. The first one is easy access to carbohydrate calculation, the next is easy access to relevant guides and information, and the third one is what to do in an emergency.

Besides these findings, it was also clear from our interview with the children that they wanted a solution that they could carry with them all the time. The children already have access to an app that counts carbohydrates, provided by the Danish Diabetes Association. But this app does not provide its users with sufficient options or a large enough database to support self-management. Inspired by this app, our aim was to come up with a digital solution that improves all aspects and functionalities, based on the identified themes and concerns from our analysis.

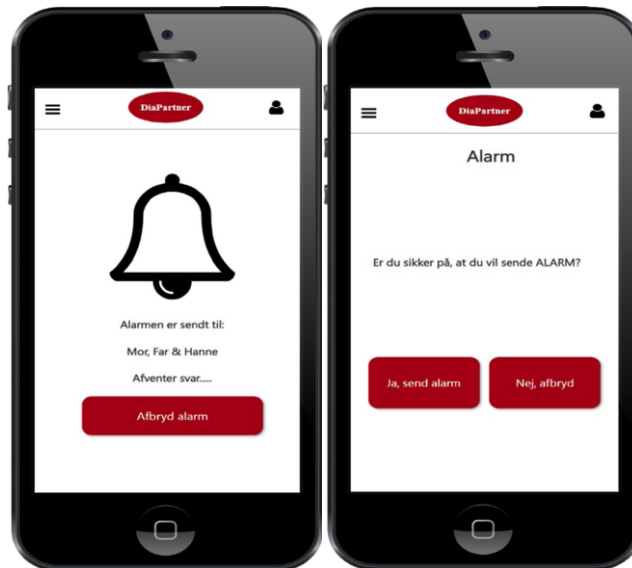

The current app is not easy or fast to use in counting carbohydrates. For example, the application should provide the users with a larger database of food and beverages that must be easy to navigate and the users must be able to select specific kinds of food and beverage as "favorites" (see Picture 1).

Picture 1. Show product and save as a "favorite"

Furthermore, the application had to inform and provide advice about type 1 diabetes, not only to enlighten its users (the children with diabetes), but also to provide the network with an easy and accessible way to learn about the disease. Thus, it was a main concern for the parents that e.g. school teachers, sports association leaders and others did not have the necessary knowledge about diabetes to take care of their child. Therefore, the child could not participate in social events like summer camps and sleepover parties. An important part of this issue is also a specific guide on how to handle a hypoglycemic incident

Another result of the data analysis showed that there is a need for a function that could help the children and their parents to feel more confident that they will get help quickly if needed, especially when the children are away from home. Therefore, we decided to incorporate an alarm. To do so, we had to include and activate the phone's GPS, which caused several ethical questions whether the purpose of the application is to support the children's self-management—not for the parents to be able to track them. Instead of activating the GPS all the time, we developed the ALARM function so the users (children with diabetes) could include three different emergency contacts. If the alarm is triggered, these contacts receive a message with the child's location (see Picture 2).

Picture 2. ALARM

In summary, the design proposals point to a relatively simple solution that particularly addresses the demands of children for easy access to carbohydrate calculations and the parents' requirements for security and access to relevant information for networks and friends.

4. Discussion

The analysis of the data from the health professionals, parents, and children revealed very different foci about what is important in digital support for children and adolescents

with type 1 diabetes. The workshop with health care professionals resulted in three design suggestions: a digital diabetes diary, an interactive understanding of diabetes, and the implementation of virtual reality to build bridges between parents and children. The parents' concerns were connected to the security of their children; for example, "how much responsibility should be given to a 7-year-old?" and "are the teachers aware of how to help and support my child?" Also, the parents assumed that the children would like to participate in an online community. The children, however, were not interested in digital diaries, augmented reality, or online communities. They wanted an optimization of a carbohydrate app that could help them manage their diabetes, provide security when on their own, and offer information when needed. As stated above, our study shows the importance of putting the end-users and their daily life situation at the center when designing new applications.

Does Health-IT Improve People Centered Care?

Pernille BERTELSEN¹, Lone Stub PETERSEN¹ and Christian NØHR²

¹Aalborg University, Department of Planning, Danish Centre for Health Informatics,

²Maersk Mc Kinney Moller Institute, University of Southern Denmark, Denmark

Abstract. Patient involvement can be supported in many ways, some of these through health IT (HIT). Health care practice is changing with digitalization and technologies that patients can use to generate data outside the formal health facilities are growing. Inequality affect citizens ability to participate. There is a need to be mindful of the perceptions and the willingness of citizens and the health care professionals to meet this change. Selected data from two Danish surveys, highlight the citizens and health care professional's perspective on health IT. From the analysis emerge central considerations on what to be aware of in the future development of HIT.

Keywords. eHealth, Survey, Citizens, Clinicians, Equality.

1. Introduction

1.1. Strategy and practice

In line with the WHO global strategy on people-centered and integrated health service [1] the latest Danish Digital Health Strategy 2018-2022 emphasize that: "Patients should be more involved in their own treatment, so that the health system interacts with the patients on his/her own terms" [2] (p.21). Throughout the strategy we can read an increased focus on the involvement of the patients and an interest to increase the support to them and their relatives "... in taking greater ownership of their own illness in their daily lives ..." [2] (p.18).

There is a general international interest in the use of what is termed patient generated health data (PGHD), in the healthcare sector [3]. The availability of technological solutions makes it possible for citizens and patients to collect data themselves. This is one of the ways of framing patient involvement through HIT. However, equality and inequality aspects of HIT is not predominant.

The strategy recognizes that in the formal health care system there are relatively few experiences using data collected by the patient's own equipment but also "that the areas where apps, medical devices and medication converge are currently shifting" [2] (p.24). Hence there is a need to develop a shared framework that allow patients to start using devices and apps and share their data with the health care system. A central notion is to combine the potential of HIT and PGHD to improve service and reduce costs. However, in Denmark and in most other countries little is known about what type of technologies citizens use, and which social groups use the technologies as well as how clinicians and

citizens recognize and use digital health care [4]. Here we explore the different perspectives on the use of patient generated health data from selected questions in two different surveys.

Present-day, we see small devices sensing a range of vital measures among average consumers allowing them to track their own health data. It is no longer exclusive toys for more well-off first movers [3]. Although the potential in PGHD and health apps for mobile devices is immense a German study shows that a substantial proportion of the population is not engaged [5]. They conclude that although there are many health app users a substantial proportion of the population are not engaged. They suggest that socio-economic-related and literacy-related disparities as well as motivation to change should be considered by app developers and researchers. A Study from US show that Collage education has a significant positive impact on eHealth behaviors [9]. Nonetheless, as stated in the Danish digital health strategy, it still remains to work out how best to integrate these data into contemporary clinical work, and as emphasized by [5], to make sure those in most needs also are those being encouraged to collect own health data and thus benefitting from the use of the health data.

To direct the future development of citizens centered health apps it is necessary to have more knowledge on who the actual users of health apps are, and knowledge on the health providers attitudes towards citizens using these tools and services.

2. Methods

Selected questions from two different studies were used to analyze the citizens' experiences with accessing and using health information systems, and health providers attitudes to opportunities for patients' use of information systems and the impact of these systems on patients' engagement in personal health.

2.1. Citizen survey

The 2017 citizen survey reported from in this paper is the third in a bi-annual series of National surveys on Danish citizens' expectations and perspectives on eHealth. A questionnaire was developed by the authors and a Danish market research agency (Megafon), was commissioned to administer the surveys, on a population sample of $n=1059$. The survey is combinational using both email and telephone. The selected respondents are part of a citizens' panel reflecting the Danish adult population with respect to age, education and geographic distribution. The questionnaire consists of 10 demographic background questions (Age, gender, education, state of health, etc.) and 39 questions about their relations and attitudes towards their use of e-health technologies (hardware, service used, etc.). Data from three questions are reported in this paper.

2.2. Clinician survey

The 2017 study of clinicians use of health information systems has been conducted for 9 consecutive years. Questionnaires was distributed to medical doctors, nurses and medical secretaries with the help from their respective professional associations. Random samples (in average 10.000) from their member files received a link to a web-based questionnaire. An average response rate of 23% was achieved over the 9 years of study. The questionnaire consists of 7 background questions (Age, gender, education, seniority,

medical specialty etc.) and 48 questions about their use of specific systems, their user experience (Ux) and attitude towards e-health in general. Data from one question is reported in this paper.

3. Results

3.1. What is the educational background of the citizens using e-health?

There is a clear majority of citizens with a master level university education that are using e-health services to monitor their health or seek health advice (Figure 1). 48% were familiar with one or more of these services compared to 29 % of those with elementary public-school education.

Figure 1. Number of citizens who indicate they have used e-health services to manage their health (e.g. sleep monitoring, smoking cessation, nutrition or exercise).

There are 59% to 64% of citizens who expect that the use of health-IT will improve the quality of the healthcare services they get. Only 10% -12% are concerned that it might impair the quality of health care services. About every four indicate that they have not made up their mind. As shown in figure 2 the attitudes have been quite stable in the period where the studies have taken place.

Figure 2. Citizens expectations to whether the use of health-IT will improve or impair the quality of the healthcare services they receive.

In the question of clinicians’ attitude to citizens potential benefits of the national health-IT, almost one third indicate that they do not think the health-IT initiated by the national initiatives will improve the citizens engagement in their own health situation

(Figure 3). Of these just under 8% disagree strongly. On the other hand, more than 20% agree that health-IT can enhance the citizens engagement in health issues, of which only just over 1% strongly agree. More than half of the responding clinicians indicate a neutral attitude, or they don't know.

Figure 3. Clinicians attitude to the statement: The national health IT initiatives will strengthen the citizens engagement in their own health

When clinicians are asked about their opinion on how patient can benefit from health-IT by having improved capabilities to master own diseases more than 30% strongly disagree or disagree (Figure 4). Half of the responding clinicians are neutral, or they don't know. Only 18% indicate they strongly agree or agree. This question was not part of surveys before 2015.

Figure 4. Clinicians response to the statement: I believe that the digital tools we provide to the patients give them better options to master own diseases. (2017, in %, n=1144)

4. Discussion

The objective of this paper was to provide insight into citizens and clinicians perspective on HIT. Despite a well-developed Danish health care service high inequality in health pertains [6]. Our data shows how the citizens with highest education have used e-health services more than twice as much as citizens with the lowest education (26% vs 10%). This, notwithstanding the fact that those citizens in most need of health care service are to be found among those with lowest education [7]. This result is very much in line with the data from the German study [5], that also find a socio-economic difference in the use of HIT, and call for strategic awareness among health care managers and e-health system developers on how to target those citizens in most need of health care when developing

HIT interventions? Awareness of how to beat inequality in use at an early stage when designing health IT is needed. Health inventions need to be context sensitive in its design and need to be supported by health care professionals, to have high impact [8]. We claim this should also be considered for development of HIT. The demographic development, comorbidity, increased expenses should work as enough incentives.

Further, data show that citizens and clinicians have different opinions on the role that HIT can play to enhance citizens engagement and ability to master own disease. Citizens express a far more positive predictions than clinicians as to whether HIT initiatives will strengthen the citizens engagement in their own health or not.

Clinicians also express a dis-satisfaction with the available HIT tools, as to whether they actually do give a better option for the patients to master their health. Whether this view is nourished by clinicians' experience of patient's difficulties in handling HIT tools available today, or from their own disbelieve in HIT tools, are not known but could be further investigated by qualitative research methods. The HIT technology needs to be understood as a socio-technical intervention and therefore, designed and targeted with attention to the context of its use and its users. Finally, we like to draw attention to limitation being the difficulties we have faced in getting a high response rate in the self-selected clinician survey. However, this is not specific for our study but common for this type of studies.

^d*University of Texas Health Science Center at San Antonio, TX, United States*

Abstract. Directly extracting data from site electronic health records for updating clinical trial databases (eSource) can reduce site data collection times and errors. We conducted a study to determine clinical trial characteristics that make eSource vs. traditional data collection methods more and less economically attractive. The number of patients a site enrolls, the number of study data elements, study coordinator data collection times, and the percent of study data elements that can be extracted via eSource software all impact eSource economic attractiveness. However, these factors may not impact all clinical trial designs in the same way.

Keywords. economic analysis, clinical trial, data collection, eSource, HL7 FHIR

1. Introduction

The complexity of clinical trial protocols continues to increase and is associated with higher clinical trial total and per patient costs [1]. Site-related costs account for 70% of late phase clinical trial total costs [2]. While remote monitoring has been shown to reduce site management costs by reducing the number of on-site monitoring visits [3], there has been less success in reducing costs associated with site personnel workload. Directly extracting data from site electronic health records (EHRs) for updating clinical trial databases (eSource software) has been shown to reduce site data collection time and errors [4,5]. However, previous studies did not consider the costs of the informatics infrastructure needed for sites participating in eSource-enabled clinical trials.

Decision analytic methods are used to simulate complex decisions by combining disparate data sources [6,7]. These tools are particularly useful where there is uncertainty regarding key decision parameters. We conducted a study to determine which clinical trial characteristics make eSource-enabled versus traditional data collection methods more and less economically attractive for clinical trial sites.

¹ Corresponding Author E-mail: eric.eisenstein@duke.edu.

2. Methods

Model Design: We developed a decision analytic model to compare per patient total data collection costs for eSource-enabled vs. traditional data collection methods at clinical trial sites. Our base case model uses characteristics of the TRANSFORM-HF clinical trial [8]. Briefly, TRANSFORM-HF is a 6000 patient, 50-site pragmatic clinical trial to evaluate the use of two loop diuretic medications in patients hospitalized for new or worsening heart failure. Sites in this trial are responsible for collecting information related to the patient’s enrolling hospitalization and a centralized call center conducts follow-up patient interviews.

Decision Model Structure: The decision analytic model used here was constructed to evaluate two data collection strategies: eSource-enabled and traditional (i.e., manual data abstraction from medical records by humans). During the patient’s enrolling hospitalization, three types of data collection occur: (1) a study coordinator collects and enters hospitalization data, (2) the study coordinator resolves queries regarding those data, and (3) an on-site monitor verifies selected cases against the source data. Queries are divided into those that can be resolved while the study coordinator is still in the patient’s EHR and those subsequent queries that require the study coordinator to reopen the patient’s record in the EHR. The study’s model includes four types of measurement data: (1) clinical trial site characteristics, (2) study personnel costs and productivity, (3) eSource costs and productivity, and (4) study outcomes.

Clinical Trial Characteristics: Our model includes six clinical trial site characteristics: (1) number of patients enrolled, (2) number of data elements collected for the study database, (3) percent of study data elements that are FHIR accessible (can be accessed via eSource software using the HL7 Fast Healthcare Interoperability Resources (FHIR) standard) [9], (4) number of queries generated, (5) number of onsite monitoring visits and (6) number of cases reviewed per monitoring visit (Table 1). The TRANSFORM-HF study design assumes that each site will randomize 120 patients on average during a 24-month enrollment period.

Garza et al. identified 155 unique TRANSFORM-HF data elements of which 82 (52.9%) could be mapped to the US Common Core and would be accessible using HL7 FHIR [9]. In a review of 14 protocols for which study data were managed by our institution, queries were generated for 1.5% of study data elements. Based upon operational experience with multicenter studies coordinated by our institution, approximately, 67% of these queries would be resolved during initial data entry while the site coordinator was in the patient’s medical record and 33% would be resolved after initial data entry was completed, requiring the patient’s medical record to be reopened and reexamined. We assumed a risk-based monitoring strategy where each site would have one monitoring visit, 30% of sites would have a second visit and 10% of sites would have a third visit (average 1.4 visits per site). We also assumed monitors would verify source documents for 5 patients per visit (average of 7 cases for all visits).

Table 1. TRANSFORM-HF Clinical Trial Characteristics

Variable	Estimate	Range Tested (+/- 50%)	Data Source
Patients randomized	120	60 to 180	Protocol (Ref 8)
Study data elements	155	78 to 232	Garza (Ref 9)
FHIR accessible rate (%)	52.9%	27% to 79%	Garza (Ref 9)

Study Personnel Costs and Productivity: We used keystroke level modeling to estimate the number of data elements a study coordinator would collect and enter per hour for (1) initial data entry, (2) query resolution during initial data entry while in the patient’s medical record and (3) query resolution after initial data entry requiring the medical record to be reopened and reexamined (Table 2). Keystroke level modeling estimates the length of time an expert will take to accomplish an interactive computer system task without errors [10,11]. We then estimated the number of data elements site personnel would map and confirm to FHIR resources per hour as well as the hourly costs for study site and monitoring personnel. Although site monitors typically are paid by study sponsors (and are not included in site personnel costs), we included monitoring costs to obtain estimates of all data collection costs incurred at clinical trial sites. Hourly costs were estimated by inflating annual salary costs by a 35% fringe benefit rate and 50% indirect costs. Based upon our experience, we assumed personnel could allocate a maximum of 30 hours per week to specific projects.

Table 2. Personnel Characteristics

Variable	Estimate	Source	
TRANSFORM-HF			
Site coordinator data collection rate	134 data elements per hour	Keystroke level model	
Number of queries resolved			
While in patient’s medical record	134 data elements per hour	Keystroke level model	
No longer in patient’s medical record	106 data elements per hour	Keystroke level model	
FHIR Mapping			
Data element mapping	10 data elements per hour	Observation	
Data element mapping time	15.5 hours	Computation	
Data element confirmation	30 data elements per hour	Estimation	
Data element confirmation time	5.2 hours	Computation	
Personnel Costs	Annual	Hourly	
Site principal investigator	\$200,000	\$260	UAMS
Site study coordinator	\$80,000	\$104	UAMS
Information technologist	\$65,000	\$84	UAMS
Information security officer	\$100,000	\$130	UAMS
Site monitor	\$80,000	\$104	UAMS

*UAMS is the University of Arkansas for Medical Sciences

eSource Costs and Productivity: eSource software implementation costs have fixed and variable components. The fixed costs are incurred to set-up a trial and the variable costs are incurred per study data element. Fixed costs include (1) study materials presented to site team members and (2) site eSource security review/approval, setting up the EHR research record, connectivity testing and eSource user training. Variable costs include the time to map study data elements to site EHR FHIR resources and to confirm those mappings. For study material presentation and review, we estimated the site principal investigator, site study coordinator, an information technologist and the site security officer each would require 5 hours (20 total hours, \$2890 cost). For eSource security, we estimated the site coordinator would require 7 hours, the information technologist 4 hours, and the security officer 4 hours (15 total hours, \$1584). Lastly, we estimated the site coordinator and information technologist would require 15.5 hours each to map the TRANSFORM-HF data elements (n=155) to EHR FHIR resources, and the site coordinator would require an additional 5.2 hours to confirm these mappings (36.2 total hours, \$4474 cost) (Table 2).

Study Outcomes and Analyses: The primary study outcome is total per patient data collection costs for each strategy (eSource-enabled and traditional). Secondary outcomes include the major components of total costs and study coordinator costs. The study’s model estimates primary and secondary outcomes and sensitivity analyses. For each data collection strategy, we consider the lower cost strategy to be preferred. Sensitivity analyses investigated the impact of 50% increases and decreases in clinical trial characteristics upon per patient data collection costs. These analyses also identified threshold values for clinical trial characteristics that make eSource-enabled the preferred data collection strategy vs. traditional data collection.

3. Results

Cost Outcomes: The study’s model estimated TRANSFORM-HF per patient total data collection cost was \$10 lower for eSource-enabled versus traditional methods (\$119 vs. \$129) (Table 3). Coordinator costs were \$68 lower (\$61 vs. \$129) while the per-patient cost for eSource software implementation was \$58 higher. Thus, for a site that could enroll 120 patients over the 24-month accrual period, investing in eSource infrastructure would be marginally economically attractive. Coordinator cost savings included \$64 for initial data collection, \$1 query resolution, and \$4 onsite monitoring.

Table 3. TRANSFORM-HF Cost Outcomes

Cost Outcome	Data Collection Method		Difference
	eSource-Enabled	Traditional	
Total Costs	\$119	\$129	(\$10)
Coordinator component	\$61	\$129	(\$68)
eSource component	\$58	\$0	\$58
Coordinator Costs			
Initial data collection	\$57	\$120	(\$64)
Query resolution	\$1	\$2	(\$1)
Site monitoring	\$3	\$7	(\$4)

Sensitivity Analyses: The benefit of eSource-enabled vs. traditional data collection in TRANSFORM-HF clearly was influenced by clinical trial characteristics (Table 4). With a small number of patients, a small study database (number of data elements), a lower FHIR accessible rate (percent study data elements accessible via eSource software), and a higher site coordinator data entry rate, the use of eSource vs. traditional data collection would not be cost saving. However, at higher values for these parameters, the use of eSource software becomes much more economically attractive.

Table 4. TRANSFORM-HF Sensitivity Analysis

Variable	Less 50%	Strategy Cost Difference	Plus 50%	Strategy Cost Difference	Break Even Value	Total Strategy Cost
Number of patients	60	\$45	180	(\$28)	102	\$130
Study data elements	78	\$14	232	(\$33)	123	\$102
FHIR accessible rate	27%	\$35	79%	(\$55)	47%	\$130
Data elements / hour	67	(\$74)	201	\$12	158	\$111

4. Discussion and Conclusion

Our results demonstrate that eSource-enabled vs. traditional data collection methods can be cost saving for the typical TRANSFORM-HF clinical trial site. Our decision analytic model estimated a \$68 per patient reduction in site coordinator data collection costs and a \$58 per patient increase in eSource-related costs. However, these results vary greatly depending upon the number of patients a site enrolls, the number of study data elements and the percent of those data elements that are accessible via HL7 FHIR.

Our study was confined to the economics of sites contemplating the use of eSource software. This work contrasts with the EHR4CR cost-benefit analysis that took the pharmaceutical company perspective [12]. We believe the site perspective is both important and under-investigated. If the use of eSource is not economically attractive for sites, adoption of this technology is unlikely unless clinical trial sponsors include additional study start-up compensation.

If eSource-enabled clinical trials are to become a reality, clinical trial coordinating centers and sites will need to have personnel with the requisite skill sets to implement and manage eSource software. Our model omitted potential eSource benefits such as greater data quality and shorter clinical trial durations. Nonetheless, we believe we have started an important dialogue that could lead to greater recognition of the value of eSource-enabled data collection as we learn more about the ways in which clinical trial design factors drive the economics of eSource-enhanced data collection.

^c*Finnish Institute for Health and Welfare, Finland*

Abstract. Online symptom checkers and assessment services are used by patients seeking guidance on health problems. In this study, the goal was to identify health professionals' experiences of the benefits and challenges of new symptom checkers providing triage advice. Data was collected through an online survey of 61 health professionals who were target users of the online symptom checkers implemented in six public health organizations and one private occupational health clinic. Most of the health professionals supported the use of online symptom checkers and found services useful to patients because they provided patients quick contact with health professionals and referral to care or self-management instructions regardless of time and place. Health professionals were less confident that most of the patients were capable and willing to use the symptom checkers. Health professionals were satisfied with symptom checkers providing them with more useful information before meeting patients. By contrast, symptom checkers were seen as disrupting clinical work and time-consuming. The results imply that the clinical work processes should be redesigned to guide patients in an efficient manner, avoid work overlap, and provide work motivation for professionals.

Keywords. Online symptom checkers, triage advice, health professionals

1. Introduction

Online symptom checkers and assessment services are used by patients seeking guidance on health problems [1]. Using computerized algorithms, symptom checkers ask patients questions about their symptoms, provide them with a potential diagnosis, suggest self-care, and direct them to the appropriate care setting [2]. The goal is often to supplement or replace resource-intensive telephone triage lines. The online symptom checkers also have the potential to support self-care and decrease the number of unnecessary visits.

Based on Chambers' et al. [1] recent literature review, the evidence of the diagnostic accuracy and impacts of online symptom checkers remains weak. Triage advice provided by symptom checker algorithms tended to be more risk-averse than that given by health professionals. Thus, symptom checkers may encourage patients to seek care in cases where self-care would be more justified [2]. In addition, younger and more highly-educated people are more likely to use online symptom checkers, whereas older and less

¹ Sari Kujala, Corresponding author, E-mail: firstname.secondname@aalto.fi.

educated patients are more likely to prefer telephone or face-to-face contact [1]. Thus, health professionals through their endorsement play an important role in supporting patients and increasing their trust in technical solutions [3]. If only younger and more highly educated patients use online symptom checkers, the cost-effectiveness goals of these services may not be reached, and health equity issues may arise.

In Finland, a joint project of 14 of the largest cities and hospital districts have been developing a patient portal called Omaolo. The three main services include an online symptom checker called Oirearvio, a patient self-assessment and well-being coaching, and a health care plan. In spring 2017, health professionals' pre-implementation expectations relating to the patient portal were studied through an online survey [4]. Most of the 2,943 respondents (74%) expected benefits for patients; however, many expressed concerns that patients were unwilling or unable to use the new service. As symptom checkers are a new kind of health technology and the personnel appear to have concerns, it is important to follow-up on their implementation. Follow-up activities were also found to be generally important to support personnel during change, avoid resistance, and remove barriers [5].

In 2018, healthcare organizations started to use online symptom checkers, which were the first finalized functionality of the patient portal. The symptom checkers do not provide diagnosis, but they are used to direct the patient to obtain appropriate care or provide self-care instructions. The symptom checkers were designed for specific conditions: low back pain, urinary tract infection, and upper respiratory tract infection. The goal of this survey study was to identify health professionals' first experiences of using symptom checkers. Findings provide a better understanding of the role of symptom checkers in clinical work and the views of health professionals' relating to the benefits and challenges of the system.

2. Methods

An online questionnaire was developed to identify the experiences of health professionals, including nurses, physiotherapists, and physicians. The questionnaire was a new version of the previous expectation questionnaire including both multiple-choice and open-ended questions [4]. Health professionals were asked to evaluate their current experiences (instead of expectations as in the previous questionnaire), and the wording was changed from future to present tense.

The questionnaire included existing validated survey items for measuring professionals' support for the symptom checkers [6], their usability [7], and their influence on professional autonomy [8]. In addition, the participants were asked to rate whether the symptom checkers had brought the planned benefits to their work and patients and whether good implementation practices were used in their organization. The scales ranged from 1 (fully disagree) to 5 (fully agree) and included a sixth option, 6 (I do not know), which was removed from the analysis. Two open-ended questions were related to the benefits and challenges of the symptom checkers. In the background questions, participants were also asked how often they had used the symptom checkers. The quantitative data were with using descriptive statistics, and the responses to open-ended questions were content-analyzed.

The data was gathered from December 2018 to March 2019. The survey invitation with the link to the questionnaire was sent to health professionals identified by the local project managers as potential users of the symptom checkers. The respondents

represented six public health organizations and one private occupational health clinic that was located in the largest cities of Finland. The seven organizations were selected for the study as they were the first ones to adopt the symptom checkers. Although participation was anonymous, respondents could submit their email address at the end of the survey to participate in a draw for 10 movie tickets.

3. Results

A total of 61 health professionals answered the questionnaire; the response rate was 15.2% in six of the organizations (unfortunately, we were unable to identify a response rate for one organization). The mean age of the respondents was 43.8 years (SD = 10.4), and 87% were female. Most of the respondents (77%) were nurses, 15% were physiotherapists, and 7% physicians. The use of the symptom checkers was not yet very established: Most of the respondents (41%) had used them one to two times per month, 39% weekly or daily. Furthermore, 18% had only tried, and one respondent (1.6%) had not used them at all. A few of the respondents also commented that the symptom checkers were not yet widely used among patients.

Most of the health professionals (88.5%) agreed that they supported the use of online health checkers. The majority of them also agreed that the symptom checkers resulted in planned patient benefits (Table 1). In particular, respondents believed that the symptom checkers improved the availability of the services. However, the respondents were clearly less confident that most of the patients were capable and willing to use the symptom checkers.

Table 1. Percentage of health professionals agreeing with the statements related to the patient benefits of the symptom checkers.

Patient benefit	Professionals agree (%)
The symptom checker improves the availability of the services.	79
By using the symptom checker, patients have the same criteria to receive care.	68
The symptom checker supports individual care.	62
I believe that over half of the patients are capable of using the symptom checker.	50
I believe that over half of patients are willing to use the symptom checker.	42

Table 2. Percentage of health professionals agreeing with the statements related to the benefits of the symptom checkers for their work.

Benefit for professionals' work	Professionals agree (%)
Using the symptom checker provides me with more useful information before meeting a patient.	67
The symptom checker leaves more time for meeting with patients.	45
The symptom checker reduces the amount of routine work in my tasks.	38
The symptom checker reduces my work.	33
The symptom checker decreases my control over the patient process.	16
The symptom checker decreases my control over professional decisions.	12

Most health professionals also agreed that the symptom checkers were useful for their work because it provided more useful information about patients before meeting them (Table 2). However, less than half of them believed that the symptom checkers

would be efficient in their work. A minority also believed that symptom checkers decreased their control over the patient portal and professional decisions.

In open-question responses, the most often mentioned benefits included the following: a) patients will be guided to the right professional (a nurse, physiotherapist or doctor), b) patients get quick help and standardized self-management instructions, c) there will be less unnecessary visits, fewer phone calls, and less queuing. The most often mentioned challenges were related to the changes that the new symptom checkers brought to work, responsibilities, and common work processes. The symptom checkers were seen as added work, as they created one more channel to handle, and some respondents mentioned that patients started to unnecessarily use several contact methods. Many were also concerned that not all patients were able to use computers or the symptom checkers and believed that the care instructions should be made easier so patients could understand. For example, one respondent mentioned that the symptom checkers required more work than a phone call because patients did not know how to use them. Furthermore, the symptom checkers were seen as needing development, as they did not notify nurses when a patient made contact, and they also required extra work as nurses needed to transfer patient health information to a separate system.

4. Conclusions

The majority of the health professionals had a positive view of the new online symptom checkers. Most of them accepted the use of online symptom checkers, and they found that the services were useful to patients because they provided patients with a method of quick contact with health professionals and referral to care or self-management instructions, regardless of time and place. Health professionals valued the fact that the symptom checkers provided them with more patient information before meeting patients. Some of the professionals also saw opportunities to save resources as patients were immediately guided to see the right professional and, in some cases, patients could manage the health issues by themselves.

On the other hand, the symptom checkers clearly challenged existing work practices and the roles of health professionals. Health professionals believed that symptom checkers created extra work for them, considering that the services offered patients a new channel to contact health professionals. Some of the health professionals believed that the symptom checkers were a threat to their professional autonomy as they reduced their control over the patient process and professional decision making. Previously, this perceived threat was found to have a significant negative influence on health professionals' acceptance of new technology [4,8]. Furthermore, in our studied organizations, a minority of the health professionals resisted the new symptom checkers. Thus, there is a risk that teams would not work optimally and some professionals would not recommend the symptom checkers to patients.

The results imply that the implementation of symptom checkers, new work processes, and division of work require special attention in health organizations. Health professionals need support and training for this novel situation, and work processes should be redesigned to guide patients efficiently, avoid work overlap, and ensure work motivation among health professionals. The technical solutions should support health professionals' work in a holistic manner, so that they are not separated from other systems used and that incoming messages notify the responsible person.

Successful implementation of symptom checkers also requires patients to be engaged and motivated to use them. The variety of patients and their skills makes this challenging. Respondents indicated that patients lacked skills to use computers and symptom checkers. Although the content of the symptom checkers was built on scientific evidence, it is possible that they could lead to wrong conclusions if patients misinterpret the questions used. Furthermore, one respondent commented that the symptom checkers appeared to create concerns and lack of support among patients. Thus, it is important that symptom checkers are easy to understand and use. In addition, patients' experiences should be studied to identify their support needs and barriers of use.

The sample size of this survey study was relatively small as the online symptom checkers were used less than one year in a few organizations. This study focused on health professionals' subjective experiences in the early phase of the adoption process. As health professionals and patients will gain more experience in using the online symptom checkers, usage may become more routinized and smoother. However, providing a better understanding of the health professionals' views of symptom checkers, and their benefits and challenges will help developers in designing technical solutions and health organizations in supporting the adoption of the new services.

Acknowledgements

How Come Nothing Changed? Reflections on the Fasting-Time Project

Morten HERTZUM^{a,1} and Jesper SIMONSEN^b

^aUniversity of Copenhagen, Copenhagen, Denmark

^bRoskilde University, Roskilde, Denmark

Abstract. Many healthcare interventions fail to produce the intended effect. In this paper we look back at the fasting-time project, which aimed to shorten patients' preoperative fasting times. However, the project failed to achieve this effect, even though it had been identified and prioritized by the clinicians at the studied hospital. A set of mutually reinforcing factors collectively explain why the project failed to produce change. The four main factors are: lack of urgency, risk aversion, day-to-day busyness, and lack of managerial commitment at the department level. The simultaneous presence of these factors complicates efforts to counter them.

Keywords. effects realization, implementation, change management, fasting time

1. Introduction

It is nontrivial to improve hospital practices by introducing new information systems and new ways of working. Diffusion-of-innovations theory states that for an innovation to be adopted it must, among other things, be compatible, avoid complexity, provide relative advantage, and be actively championed by people such as opinion leaders [1]. Technology-acceptance research finds that for systems to be adopted and used they must be perceived as useful, easy to use, and even enjoyable [2]. Reviews of the implementation of electronic health records confirm many of these factors and add factors such as adaptability, data migration, implementation climate, management, organizational readiness, planning, staff training, and external policy and incentives [3][4]. In this study, we look back at a project that failed to produce the intended effect, even though the clinicians had themselves identified and prioritized this effect.

The project [5] concerned the reduction of patients' preoperative fasting times. To reduce the risk of pulmonary aspiration due to vomiting during anesthesia, patients must fast for six hours prior to surgical operations. Fasting times in excess of six hours should, if possible, be avoided to reduce postoperative complications and patient discomfort. But avoiding fasting times in excess of six hours presupposes efficient coordination among the involved clinicians. Organizationally, the fasting-time project was to introduce new procedures for recording fasting times and acting on long fasting times. Technologically, the project was to utilize a network of electronic whiteboards for recording, and visualizing, how long the individual patient had fasted. In the following, we first summarize the method and results of the project, then we reflect on why the project failed to produce shorter preoperative fasting times.

¹ Corresponding author; hertzum@hum.ku.dk.

2. Method

The effort to improve the coordination of operations, and thereby reduce fasting times, was a participatory-design project conducted by the authors and a group of staff from a hospital in Denmark. The project followed an effects-driven approach [6]. That is, the project consisted of specifying the purpose of the project in terms of an effect, realizing this effect through technical and organizational changes, assessing the extent to which the specified effect had been achieved, and iterating to achieve a fuller realization of the effect. Table 1 gives the timeline of our empirical activities.

We started with four workshops (a total of 10 hours) during which clinicians from different departments and staff groups at the hospital specified and prioritized the effects to be achieved in the project. The effect of reducing preoperative fasting times received top priority. After these workshops, a small group was established. It consisted of the authors, three staff members (a nurse from the operating ward and a secretary from each of the two surgical departments), and a research assistant. This group met for 16 participatory-design meetings (35 hours) to realize and assess the fasting-time effect. In between the meetings the three staff members worked to implement the group’s decisions in their departments. The group meetings were supplemented with observation (70 hours) of how the operations were coordinated at the hospital. During the effects assessment, fasting times were recorded and visualized for three months.

Table 1. Timeline of the empirical activities, which spanned the period September 2014 – December 2015

Date	Activity
<i>Phase 1: effects specification</i>	
Sep 18	Workshop with 5 clinicians and a hospital IT project manager to specify effects
Sep 26	Workshop with 10 clinicians and a hospital IT project manager to specify effects
Nov 7	Workshop with 7 clinicians to specify effects
Dec 12	Workshop with 9 clinicians to prioritize and elaborate effects
<i>Phase 2: effects realization</i>	
Feb 17	Group meeting to kick off the realization of the fasting-time effect
Feb 20	Group meeting to plan the project activities and begin defining fasting time in detail
Feb 26	Observation at surgical departments to get a sense of the coordination of operations
Feb 27	Observation at operating ward to get a sense of the coordination of operations
Mar 6	Group meeting to define fasting time (and how to record it) in detail
Mar 17	Workshop with whiteboard vendor to configure the fasting-time fields
Mar 27	Group meeting to devise a standard procedure for the recording of fasting times
Apr 10	Group meeting to ensure the adoption of the whiteboard fields and standard procedure
Apr 24	Group meeting to promote the project and align it with the current use of the whiteboard
May 8	Group meeting to finalize the setup of the effects assessment: the fasting-time recordings
May 22	Group meeting to organize and schedule the follow-up on the fasting-time recordings
<i>Phase 3: effects assessment</i>	
Jun 4	Group meeting to prepare the next phases and the analysis of the fasting-time recordings
May 11 - Aug 14	Fasting times recorded and visualized on the whiteboard
May 18 - Jun 30	Observation at the surgical departments of how fasting times were recorded and used
Aug 21	Group meeting to validate the fasting-time recordings and brainstorm new interventions
Sep 4	Group meeting to discuss the fasting-time recordings with department management
<i>Phase 4: effects realization</i>	
Sep 13 - Oct 4	Observation of whiteboard meetings at the operating ward (four Sundays)
Sep 18	Group meeting to analyze project progress and identify barriers that curbed progress
Oct 2	Group meeting to prepare a project presentation and discuss the whiteboard meetings

Nov 5	Group meeting to devise a renewed intervention: daily whiteboard meetings
Nov 16 - Dec 15	Observation of whiteboard meetings at the operating ward (daily for a month)
Dec 11	Group meeting to discuss lessons learned by the project group and the hospital at large

3. Results

In brief, the changes made to reduce the patients' fasting times consisted of (a) defining fasting time in meticulous detail, (b) extending the hospital-wide network of electronic whiteboards with fields showing each patient's fasting time, (c) devising a standard procedure for the recording of the fasting time on the whiteboard, (d) instituting this procedure among the clinicians, (e) bringing fasting times to the attention of staff and management, (f) adjusting the instructions given to patients about when to eat for the last time before arriving for elective operations, and (g) introducing daily whiteboard meetings at the operating ward. During the daily whiteboard meetings, the surgeons reviewed the patients scheduled for operation, fine-tuned the schedule to accommodate acute operations and reduce fasting times, and had the possibility to order a meal for patients who would not be operated within the following six hours. For more detail about the changes made to reduce the fasting times, see Simonsen et al. [5].

In the period May 11 – August 14, 2015, the fasting time was recorded for 416 (32%) of the patients who were operated upon during this period of time. The average fasting time was 12.8 hours, more than twice the required 6 hours. The top 10% of the fasting times were 18-23 hours for acute patients and 16-20 hours for elective patients. In assessing the fasting times, a chief physician expressed surprise that they were so long, especially for the acute patients. Another chief physician agreed that the fasting times were long and likely to cause postoperative complications, such as prolonged wound healing. He also asked the pertinent question: "*Who assumes responsibility for this?*" His own tentative answer was that on a daily basis no one really cared about long fasting times. Our observations of the daily whiteboard meetings, introduced to heighten awareness of fasting times, confirmed this answer: Many clinicians did not attend these meetings, and on no occasion did we observe that a meal was ordered for a patient who would not be operated within the following six hours. The fasting-time project was discontinued in February 2016 without obtaining shorter fasting times.

4. Discussion

Looking back at the project we contend that no single factor explains the failure to shorten the patients' preoperative fasting times. Rather, multiple factors interact and reinforce each other. The review by Ross et al. [4] makes a similar point, while that by Priestman et al. [3] merely catalogs single factors. The simultaneous presence of interacting factors complicates any attempt to counter the factors and make change happen. In retrospect, we identify four primary and several supplementary factors that collectively explain the outcome of the fasting-time project.

First, *the physicians did not experience an urgent need*. During the effects specification the fasting-time effect was championed by one emergency department (ED) physician in particular. This ED physician saw shortened fasting times as an indicator of improved preoperative coordination. Furthermore, this physician knew the whiteboard technology, which had been in use in the ED for three years prior to its introduction throughout the hospital. In the ED the whiteboard had spawned multiple process innovations. However, the ED physician did not become a member of the fasting-time project group, which throughout the effects realization and assessment struggled to obtain buy-in from the physicians. Shortened fasting times never became an urgent issue for the physicians for two reasons. First, it did not in itself present a

problem they perceived as a threat to their competent performance of their work. In spite of clinical evidence that prolonged fasting times cause postoperative complications, fasting times remained a matter of discomfort to the patients. Second, shortened fasting times did not tie in with a performance indicator the physicians were keen to achieve (see below). Improved preoperative coordination was not recognized as an important goal, but rather seen as a means. Using the improved coordination as a means to attract more patients (who would value waiting less) was discussed favorably by hospital management, but was not a goal that motivated the individual physicians. While lack of urgency is a recognized barrier to change [7], it is not easily dismantled.

Second, *the surgical department was not prepared to risk idle operation slots*. An idle operation slot is the situation where an operating room is ready and staffed with a surgical team but there is no patient to operate upon. One of the key performance indicators at the surgical department was to avoid idle operation slots. To achieve this goal, the operations were scheduled so that there would always be two patients ready for operation. If it turned out that the first patient could for some reason not be operated anyway, then the second could be operated instead. While this practice virtually prevented idle operation slots, it prolonged fasting times: In most cases, the first patient could be operated upon; the second was not operated until later and faced prolonged fasting as a consequence. The practice of always having two patients ready for operation was one of the up-front reasons for believing that changes in how operations were scheduled could realistically lead to shorter fasting times. However, alternative practices that shortened the fasting times increased the risk of occasionally not having any surgical patient who had fasted for the required six hours. Although this risk was small it was influential because it involved a key performance indicator. The aversion of this specific risk may be a conscious priority – filled operation slots over shortened fasting times. However, a more general risk aversion stifles any change [8] because change, by definition, upsets the status quo and thereby incurs uncertainty and risk.

Third, *the clinicians' daily schedules left few resources for change efforts*. The clinicians were busy seeing patients, ordering tests, looking up procedures, keeping records, interpreting test results, consulting colleagues, obtaining equipment, and so forth. As a somewhat extreme example, one of the surgical chief physicians routinely had parallel calendar appointments. These parallel appointments partly indicated his stressful work situation and partly increased the stress on his colleagues, who could never know which appointments he would attend. A large surplus of time for change efforts would have been inappropriate because it would have meant that the hospital was not run in a cost-effective manner. But the current state of affairs was also reproachable. The constant resource and workflow optimizations in Danish healthcare had resulted in the near absence of slack resources at the hospital. The clinicians tended to feel that all their resources were tied up in their performance of their day-to-day activities. Few had the resources necessary to engage in change efforts, such as the new practices intended to shorten fasting times. To the hospital, this meant that it was at risk of going solid [9], that is, of becoming more or less incapable of change.

Fourth, *managerial commitment was lacking at the department level*. The fasting-time project was supported by hospital top management, which advocated the project and its use of the whiteboard. Top management also met with management at the department level to obtain their commitment to the project and negotiate the terms of their participation. However, the departments enjoyed a high degree of discretion, which is common in hospitals [8]. In practice, top management could not order the departments to participate in the project, but merely ask them to do so. While the

department managers accepted the project, they remained uncommitted to it, partly due to its reliance on the whiteboards. The decision to use the network of whiteboards for recording, and visualizing, fasting time was based on the successful use of the whiteboard for such purposes in the ED. In the other departments, the whiteboard had not been similarly successful. For these departments committing to the fasting-time project would also mean committing to turning the whiteboard into a technology that was in regular use by the staff, who was already skeptical toward the whiteboard [10]. While hospital top management liked the prospect of increasing the adoption of the whiteboard through the fasting-time project, it eventually had to accept that the department managers were not going to put their weight behind the project.

In addition to the main factors discussed above, several supplementary factors also contributed to the outcome of the project. These included (a) competing priorities such as the preparations for the upcoming introduction of a new electronic health record across the hospital, (b) difficulty establishing an occasion in the planning of the operations where information about fasting times could influence decisions, (c) the limited interest in information technology among many of the clinicians, (d) the interdepartmental character of the project, which increased its organizational complexity compared to the successful use of the whiteboard within the ED, and (e) the ripple effect of incomplete fasting-time recordings on the subsequent use of these recordings in scheduling the operations, for example at the daily whiteboard meetings.

5. Conclusion

In spite of top management support, considerable participatory-design work, and good intentions, no one really assumed responsibility for shortening patients' preoperative fasting times. The identified set of mutually reinforcing factors collectively explain why nothing changed. The four main reasons are lack of urgency, risk aversion, day-to-day busyness, and lack of managerial commitment at the department level.

How to Evaluate Health Applications with Conversational User Interface?

Kerstin DENECKE^{a,1} and Jim WARREN^b

^a Bern University of Applied Sciences, Bern, Switzerland

^b University of Auckland, Auckland, New Zealand

Abstract. Application of conversational user interfaces (CUI) or chatbots to healthcare is gaining interest fueled by the rising power of artificial intelligence, increasing popularity of mobile health applications and the desire for engagement and usability. While their use is mainly justified by increasing adherence to mobile health applications and facilitating interactions with the system, the question arises: How can such systems be evaluated in a reliable manner? This paper introduces an evaluation framework for health systems whose core interaction principle is a CUI. We derive quality dimensions and attributes by collecting relevant evaluation aspects from applications that have been developed in previous work and from literature on health chatbots. The collected aspects are aggregated into six thematic categories for chatbot quality, including user experience, linguistic, task-oriented and artificial intelligence perspectives, but also healthcare quality and system quality perspectives. The framework is intended to support developers and researchers in the domain of chatbots in healthcare in selecting relevant quality attributes to be assessed before their systems are distributed to patients.

Keywords. Evaluation, Health application, Chatbot, Conversational user interface, Chatbot evaluation, Natural language understanding

1. Introduction

Mobile health applications are increasingly used by patients to collect health data, and in this way to continuously monitor personal health and to get support from a virtual personal health coach throughout the day. To realize virtual health coaches or to provide mobile health interventions, conversational user interfaces (CUI) have been gaining in interest with mobile health application developers in recent years [1]. A CUI-based system is a computer program that interacts with users using natural language (written or spoken). The aim of such a system is to simulate a human conversation. To reduce system complexity, the user input is often restricted to selecting specific predefined items (e.g. choosing options as replies). A minority of CUI-based systems allow unconstrained natural language input. Some systems use embodied avatars, while others reduce the conversation to an exchange of text messages. Among healthcare chatbots, we can recognize different application areas or scopes of use. Therapeutic or counselling chatbots provide some specific therapy such as cognitive behavior therapy (CBT) [2]. Disease or medication management chatbots support the user in managing medications, provide knowledge on medication or a disease, remind on intake, explain interactions or

¹ Corresponding Author, Kerstin Denecke, Bern University of Applied Sciences, Quellgasse 21, 2501 Biel, Switzerland; E-mail: kerstin.denecke@bfh.ch.

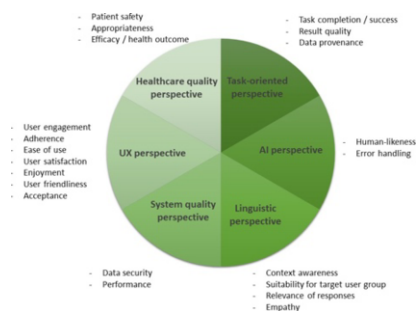

contraindications etc. (e.g. eMMA [3]). Educational applications can be stand-alone or integrated in an application with additional scope of use (e.g. psychoeducation is integrated in a CBT chatbot). Other chatbots are used for screening or collecting the medical history (e.g. Ana [4]). Several applications exist that collect symptoms from a user to make a triage. Finally, chatbots could help in retrieving information such as enabling physicians in getting the relevant information from the electronic health record of a specific patient. Depending on the scope of use of a chatbot, different quality attributes gain in importance when judging the quality. While thousands of health chatbots can be downloaded from app stores, evaluation results are reported only rarely [1]. If at all, only selected aspects are evaluated with results often not comparable due to different methodologies, evaluation aspects and metrics used [1]. In this paper, we address the question: What are the relevant aspects for evaluating healthcare chatbots? The main objective of this work is to provide guidance on relevant dimensions for evaluating health chatbots.

2. Methodology

We are focusing on mobile health applications for patients with CUI that allow unrestricted natural language user input. In previous work, we developed four such applications: eMMA – a medication management assistant [3], CLAIRE – a mobile application with virtual reality and voice user interface to educate patients [5], Ana – a system that collects the music biography as a starting point for music therapy [4] and SERMO – a mental health chatbot that helps in regulating emotions. In previous work, these chatbots have been evaluated using different methods and from various perspectives. However, their clinical effectiveness has not yet been studied. From those works, we collect evaluation aspects. Additionally, we reviewed articles on healthcare chatbots retrieved by a PubMed search with keywords "chatbot, conversational user interface, chatbot, CUI". According to a snowball approach, we added additional works starting from the retrieved results. To develop the framework, we grouped the attributes reported on healthcare chatbots and derived evaluation dimensions.

3. Results

Six perspectives emerge as important for our framework, including user experience, linguistic, task-oriented and artificial intelligence perspectives, as well as healthcare quality and system quality perspectives (Fig. 1).

3.1. Task-oriented perspective

The task-oriented perspective of a chatbot evaluation assesses the capabilities of a chatbot

Figure 1 Evaluation framework. Quality attributes fall into six thematic categories

to perform a specific task such as retrieving information, collecting specific information from a patient or predicting a diagnosis etc. It considers the degree of *task completion* or *task success* and the *result quality*. For example, a chatbot that is supposed to make a triage based on the symptoms described by a user should be assessed with respect to 1) the completeness of collected data relevant for triage and 2) the quality of the classification based on the symptoms. As such, the underlying algorithm should minimize triage classification errors and an appropriate statistic should be selected and measured (e.g. as accuracy, if the triage classes are relatively equal in frequency and in harm associated with confusion of one class for another). As a further requirement to avoid patient harm, the underlying knowledge base of a healthcare chatbot has to be evidence-based and relevant. This issue is included in the framework by the aspect *data provenance* within the task-oriented perspective. An underlying knowledge base also has to be complete with respect to the task that a chatbot is supposed to do.

3.2. Artificial intelligence (AI) perspective

The AI perspective studies to what extent the chatbot is capable of acting like a human being, e.g. in terms of problem solving or influencing a user as well as the dialogue efficiency (Note obviously, this isn't the full scope of AI, but we use 'AI perspective' as a convenient label for this focus on achieving human-like/anthropomorphic behavior). In principle, human-likeness can be studied with the Turing test. Since the Turing test cannot measure emotional engagement with users, the metric conversation turns per session has been introduced for success of social chatbots [6]. However, in healthcare applications, it is important that users are not deceived into over-reliance on a chatbot and led to failure in recognizing its limitations due to its human-like dialog. To address this issue, it could be assessed whether the chatbot implements mechanisms to determine its own intellectual limits, so that it can forward a patient to a human healthcare provider to avoid patient harm. Error handling is another aspect of relevance for healthcare chatbots within the AI perspective. It concerns the capability of a bot to react on unexpected user input or even missing data points.

3.3. System quality perspective

System quality in healthcare chatbots should consider data security and performance (e.g. answering time). Unlike patient-doctor encounters, where patient privacy and confidentiality are protected, healthcare chatbots often do not yet consider these aspects. Some of these systems even run on social media platforms such as Facebook messenger where the use of collected data is unknown to the user or captured in data policies that are long and difficult to understand and to assess. This means the data could be sold, traded or marketed by the distributor of a chatbot. To address this issue, we included data security into the framework. In existing evaluations, aspects related to system quality have not yet been reported. They include among other things that privacy policy must be provided that is application-specific and easily accessible, ideally within the application; and the treatment of confidential data of the chatbot user must be described in detail. Some of the relevant aspects can be assessed using a checklist such as to which third parties data are transmitted, and where data are stored. Further, health chatbots must comply with existing regulations such as the General Data Protection Regulation and Medical Device Regulation.

3.4. Linguistic perspective

Evaluation of a chatbot from the linguistic perspective concerns the effectiveness of a conversation. Relevant aspects include response relevance [7], context-awareness or overall dialogue quality given divergent user input. The latter addresses the fact that the language of bot responses should be suitable for the target user group, i.e. a chatbot designed for interacting with children must use different language than one for adults. Patient-doctor encounters are ideally characterized by empathy, particularly for counseling applications. Thus, a health chatbot should express *empathy* in its dialog, and this is an aspect that should be evaluated for example by adopting the interpersonal communication competence scale [8].

3.5. UX Perspective

The UX perspective evaluates an application from a human factors or usability point of view, i.e. the feasibility of a chatbot solving specific tasks. It is mainly reflecting usability issues, for example adherence, user friendliness, ease of use, appropriateness [4], user engagement [2], user satisfaction, enjoyment. The indicator *acceptance* is a new aspect that has been added to our framework and could not be found in existing healthcare chatbot evaluations. For example, acceptance could be assessed in terms of a classic technology acceptance model (TAM) [9] which combines a user's perception of ease of use along with their perception of usefulness of the technology.

3.6. Healthcare quality perspective

The healthcare quality perspective addresses patient safety, appropriateness, and efficacy or health outcome. *Patient safety* concerns evaluations studying whether the use of the chatbot might create patient harm or risks for patients. For example, a medication assistant chatbot should provide the correct dosage of the medication to be taken. *Appropriateness* of using a healthcare chatbot assesses whether it is appropriate to deliver a certain healthcare service by means of a chatbot, e.g. whether it is appropriate to deliver cognitive behavior therapy using a chatbot for a particular patient. Finally, *health outcome or efficacy* has to be assessed aligned with practice of Evidence-Based Medicine (EBM). Then the ideal is 'Level 1' evidence as produced by randomized controlled trials (RCTs). To conduct an RCT requires measurement of a relevant validated health outcome as the dependent variable, and random assignment of subjects from the target population to the health chatbot or an appropriate 'control'. How to quantify the health outcome of a mobile application depends on the medical condition and treatment it is supposed to support (e.g. quantify efficacy of a diabetes management app by comparing the HbA1c value, or scoring systems such as Patient health questionnaire PHQ-9).

4. Discussion

This paper introduced an evaluation framework for health systems whose core interaction principle is a CUI. Jadeja et al. [10] distinguished four perspectives for evaluating general domain chatbots: Information retrieval (IR) perspective, UX perspective, linguistic perspective, and AI perspective. We adapted this categorization

by broadening the scope of the IR perspective to a task-oriented perspective. Furthermore, we included two dimensions that have not yet been reported explicitly for chatbot evaluation: the system quality perspective and the healthcare quality perspective. Low quality healthcare chatbots could readily harm their users in myriad ways - such as divulging confidential data, delaying available treatment, or recommending ineffective or directly contraindicated treatment - which must be avoided. Our framework suggests attributes to be assessed for a health chatbot. We still have to assess whether relevant evaluation aspects are included related to the Medical Devices Act that have to be considered for chatbots that makes recommendations for drug administration. What is still missing are experiences on the judgement, i.e. when can we consider a health chatbot to be good or appropriate to deliver health support for real patients? Depending on the scope of use of a chatbot, some of the quality attributes suggested in the framework might become irrelevant while others gain in importance. As a next step, we start a scoping review to fortify our framework. Afterwards, a Delphi study will be conducted to collect input on how to weight the different criteria. The ultimate goal of these efforts is to provide means that help in evaluating healthcare chatbots and to ensure that only validated, evidence-based, evaluated applications will be adopted by app stores or distributed by trustworthy distributors of health applications. Experiences with implementing the framework for chatbot evaluation has to be gained. For enabling comparison among healthcare chatbots with respect to quality, agreement upon standardized metrics for the single dimensions would be helpful.

Implementation of an Open-Source Electronic Health Record for Decision-Support Education in Medical Informatics

Stephanie MEDLOCK^{a,1}, Roland SCHERMER^a and Ronald CORNET^a

^a*Amsterdam UMC, University of Amsterdam, department of Medical Informatics, Amsterdam Public Health Research Institute, Meibergdreef 9, Amsterdam, Netherlands*

Abstract. Access to electronic medical record systems is limited in many medical informatics education programs. The objective of this study was to inventory open-source patient record systems with decision support capabilities, implement a system for educational use, and test the effect of the system on students' learning. We sought systems that were under active development, with source code available, having an SQL-queryable database, and having decision support capabilities. We identified 20 candidate electronic health record systems, of which 6 mentioned decision support capabilities in their documentation. Of these, the OpenMRS system appeared to meet all of the requirements for use in our course; however, decision support capabilities needed to be added by use of a custom module implementing Arden2Bytecode, an Arden Syntax interpreter. Students who used this system showed an improvement in their knowledge of decision support systems and their capabilities. We conclude that there are a number of promising open-source electronic patient record systems currently under active development, but decision support capabilities are still immature. We anticipate further developments in this area in the coming years.

Keywords. Free and Open Source Software; electronic health record; decision support systems, clinical; medical informatics education

1. Introduction

Hospitals are moving from using a collection of small systems toward adoption of hospital-wide information systems. One of the major benefits expected from the use of electronic patient records is the ability to re-use data, for uses such as research and improving patient safety through clinical decision support systems (CDSS).

In an environment of many small medical software applications, Medical Informatics Master's students could readily build small tools which solved real information problems and gave them an active learning experience with systems similar to those that they will encounter in their career. Hands-on experience with an electronic patient record has been shown to be beneficial in health informatics education [1]. However, because most systems are closed-source, medical informatics students have no way to see how such systems are designed. This situation is further complicated by non-disclosure clauses, inhibiting the sharing of screen layouts and

¹ Corresponding Author. E-mail: s.k.medlock@amsterdamumc.nl.

interactions. Future medical informaticians will be expected to build decision support that is integrated with electronic health records; however, currently students can only get hands-on experience with stand-alone systems. With no patient record to use, students can only be educated in terms of knowledge and tested in terms of recall.

As a solution to the above problems, we propose creating a "virtual hospital" using one of the currently-available Free and Open Source electronic patient record systems. "Free and Open Source" (FOSS) means that not only is the software freely available, but the computer code which is used to make the software is also available, and is licensed so that anyone is free to make changes to the software. A number of such systems are available, including some that are in clinical use, particularly in middle-to-low-income countries [2]. However, it is not currently known if any such systems are suitable for use in medical informatics education, and particularly for teaching students about data re-use and building decision support applications.

The objective of this study was to choose a suitable FOSS patient record system with decision support capabilities, implement that system for use in Medical Informatics Master's education, and test the effect of the system on students' learning.

2. Methods

The first step was to select an electronic patient record for use. We searched for systems using an Internet search engine (duckduckgo.com) using synonyms for "open source" and "electronic patient record". This search was conducted on 1 June 2018. This was augmented by searching for lists of systems, using the names found in the first search. This process was repeated iteratively until no new systems were found. We then evaluated the documentation for these systems to assess for suitability for use in our educational program. The requirements were:

- The system should have source code available in a publicly-accessible repository.
- The repository should show current, active development (assessed by the number of contributors and commits in the last year).
- The system should be a hospital system, not a general practice system (systems which accommodate both would be accepted).
- The system should run on the Linux operating system.
- The system should have a database that is queryable in the Standard Query Language (SQL).
- Clinical decision support functionality should allow the creation of simple rule-based reminders.

The search and evaluation was carried out by one researcher (SM) with the results checked by a second researcher (RC).

Systems that appeared to meet the criteria were installed and assessed empirically to confirm that it met our needs. Once a system was selected, it was implemented on virtual machines and populated with synthetic patients. The data were generated to emulate the data quality problems found in actual patient record data: thus, the data set had missing data, data entry errors, misuse of coding systems, etc. Each group of students was made the "administrator" of a patient record system on a virtual machine. The 3-week assignment was to implement the recommendations for anticoagulant management from the ESC 2010 Guidelines for Atrial Fibrillation [3], assess the

accuracy of the advice generated by their system, and make a recommendation as to whether decision support should be implemented for the rest of the guideline.

Achievement of the learning goals was assessed through a voluntary pre- and post-test, which gave scenarios that CDSS implementers might encounter and asked the students to choose a course of action (Analyzing/Evaluating levels of Bloom's taxonomy). Students assigned to a different project served as non-randomized controls for students who completed this assignment. Statistical testing was not performed, due to the small number of students in the course.

3. Results

We identified 20 systems, of which 2 (OpenMRS and Bahmni) were judged to be suitable for use in our educational program. Bahmni is an extension of OpenMRS, thus we chose the core OpenMRS system for further investigation. Of the 20 systems identified in our search, 13 appeared to no longer be actively maintained (last commit > 1 year prior to the assessment). These systems were: FreeMed, OSCAR EMR, and openMAXIMS (last commit in 2017); ClearHealth, TolvenEMR, and UltimateEMR (last commit in 2016); Care2x (last commit 2015); WorldVisa and the Astronaut Vista installer (last commit 2014); OpenVista, LiUEEE (last commit in 2013); and OneTouchEMR and Solismed (no source code found). The other 7 systems, and the results of the assessment, are given in Table 1.

Table 1. Open-source electronic patient record systems identified by our search, and the results of assessment for suitability for decision-support education based on available documentation.

system	sourcecode repository	active development	hospital or GP	SQL variant	CDSS functionality
OpenMRS	github	303 contributors	hospital	MySQL	yes
Bahmni (based on OpenMRS)	github	78 contributors	hospital	MySQL	yes
OSEHRA Vista	github	3 contributors, 300 commits,	hospital	requires M-to-SQL	yes
OpenEMR	github	100 contributors	ambulatory	MySQL	yes
GnuHealth	gnu.org	2 contributors, 179 commits	hospital	PostgreSQL	maybe in an add-on module
OpenClinic GA	sourceforge	1 contributor, 22 commits	hospital	MySQL	unclear
Open Hospital	sourceforge	2 contributors, 80 commits	hospital	MySQL	unclear

All systems were cross-platform and thus met the criteria of being able to run on Linux virtual machines. Most systems were SQL-queryable, although derivatives of the Veteran's Administration's Vista system are written in the M programming language which incorporates a "no-SQL"-like database, and thus are not SQL queryable. Only a few systems had decision support functionality; the Vista-based systems, OpenEMR, OpenMRS, and Bahmni (which is based on OpenMRS). At the time, the decision support capabilities of OpenEMR were very simple, and it was designed for ambulatory rather than inpatient use.

Although the documentation for OpenMRS discussed support for Arden Syntax Medical Logic Modules (MLMs), an HL7-standard domain-specific language for

decision support, empirical evaluation showed no decision support capabilities in the current version. However, OpenMRS had good plugin support and used a standard interface (JDBC) to connect to its database. Therefore we were able to create a new OpenMRS addon module which supported the integration of Arden MLMs (see <https://github.com/RSSchermer/openmrs-module-ardenreminders>) using Arden2Bytecode, an existing FOSS Arden Syntax interpreter [4]. The system was hosted by a local service provider (Slash24 B.V.).

In the learning goals assessment, all 40 students completed the pre-test and 31 completed the post-test. Students who would later do the CDSS project (CDSS group, n=14) had a median pre-test score of 29% (IQR 15%-43%), while students doing other projects (non-CDSS, n=26) had a median pre-test score of 46% (IQR 34%-57%). On the post-test, the CDSS group showed a median absolute improvement of 10% (n=10, IQR 1-16%) while the non-CDSS group showed a median absolute improvement of 4% (n=21, IQR -4%-12%).

4. Discussion

We successfully incorporated an open-source patient record system with decision support in our Medical Informatics Master's program. The search for candidate systems identified 20 open-source patient record systems, of which 2 were suitable for use in our curriculum. Only 6 of the 20 systems had decision support capabilities; all of these were based on one of three core systems: OpenEMR, the Veteran's Administration VistA system, or OpenMRS. We were able to build a decision support module and implement it in OpenMRS. Assessment of students' mastery of the learning goals suggested that use of the system did aid in understanding the learning goals, although the number of students is too small to draw firm conclusions.

The strengths of our approach include a systematic assessment of the available candidate systems. However, the landscape of open-source systems is changing rapidly; this assessment should be considered a snapshot of the current state of the field. The main limitation is the small number of students in each group. Furthermore, in this year's class, we had 20 foreign exchange students, most with computer science backgrounds, participating in our class. By chance, a majority of the students in the CDSS group were foreign exchange students. This meant that only two regular Master's students completed both the pre- and post-test (with pre-test scores of 42% and 66%, and post-test absolute improvement of 12% and 15%). Although improvement for these two students was similar to that of the foreign exchange students, improvement in the CDSS group may still be attributable to the fact that the majority of these students had more room for improvement. However, it is encouraging that post-test scores on the learning goals assessment were acceptable even for students who started with little to no medical informatics background. We plan to continue to use the system and monitor its effect on learning goals, including the use of other methods for assessing learning goals.

A recent study assessed the capabilities of FOSS electronic health records, including their decision support capabilities [5]. The authors found 12 of the 20 systems that we found, plus an additional 5 systems not identified in this review (all of which appear not to be under current development or do not have source code available). They also found that OpenEMR and VistA were the systems that offered

decision support [5]. An earlier review of FOSS electronic health record systems did not assess decision support capabilities [6].

For our course, we used a custom-built decision support module integrated with OpenMRS. Previous efforts included the integration of an Arden Service, used by the Child Health Improvement through Computer Automation (CHICA) project [7]. Currently, OpenMRS does not have native decision support capabilities, but there are a number of promising efforts to add this functionality. For example, Kabukye et al. are working to develop a care pathway (including decision support) for oncology patients in low-resource settings [8]. Partners in Health is working to implement support for the triage of patients using the South African Triage System [9]. We intend to contribute to the development of other CDSS options, including integration of CDS Hooks and/or HL7 FHIR-based decision support, and we hope that future projects will include contributions from our own students to the OpenMRS code base

On the basis of this work, we conclude that there are a number of FOSS patient record systems under active development. However, the decision support capabilities of these systems are, at this time, limited. We successfully implemented an open-source patient record for teaching purposes: OpenMRS with a custom Arden Syntax module. Use of this system seemed to help students achieve the learning goals of the course. We look forward to future developments in decision support in open-source software.

The authors would like to thank the project funder, the Netherlands Initiative for Education Research Comenius program, project number 405.18865.274.

Abstract. Rare conditions can make it difficult for physicians and healthcare providers to find the right answers and treatment for patients suffering rare diseases. The number of experts specializing in rare diseases in Europe is low. In order to ensure qualified diagnosis, treatment and care for these patients, the European Commission has founded the European Reference Networks (ERNs), which are virtual networks that include healthcare providers across Europe aiming to provide better care for patients across Europe. The European Reference Network LUNG (ERN-LUNG) has been established for patients with rare respiratory diseases seeking care and advice on all aspects of rare respiratory diseases. In the context of ERN-LUNG, the Expert Advisory Board (EXABO) was implemented. EXABO is a pan-European internet platform based on a question-answering system to support answering questions regarding all areas of rare respiratory diseases. This paper gives a brief overview of the first steps taken regarding the implementation of the EXABO platform, the challenges faced and the lessons that have been learned.

Keywords. Rare Diseases, rare respiratory diseases, ERN-LUNG, Expert Advisory Board

1. Introduction and Motivation

At present, the awareness of rare diseases is increasing. Diseases that affect less than 5 in 10,000 people are considered rare [1]. Between 6,000 and 8,000 rare diseases have been identified worldwide so far and affect 6% to 8% of the European population [1]. As a result, it becomes challenging for patients and their families to receive a confirmed diagnosis and adequate treatment for their condition, as the clinicians and healthcare providers often lack extensive experience in the majority of these rare conditions. Obtaining appropriate expert advice on a disease can be highly beneficial for patients as well as the clin-

E-mail: desiree.walther@kgu.de.

icians attempting to provide a targeted therapy. Launched in March 2017, the European Commission established the 24 European Reference Networks (ERNs) that work on a range of thematic issues [2]. Their main objective is to ensure and promote excellence in care and research for the benefit of patients affected by rare diseases. The European Reference Network for rare respiratory diseases (ERN-LUNG) addresses nine rare and complex pulmonary disease groups, including Interstitial Lung Disease (ILD), Cystic Fibrosis (CF), Primary Ciliary Dyskinesia (PCD), Pulmonary Hypertension (PH), nonCF-Bronchiectasis (nCF-BE), α 1-Antitrypsin Deficiency (AATD), Mesothelioma (MSTO), Chronic Lung Allograft Dysfunction (CLAD) and Other Rare Lung Diseases (ORLD), which are represented in nine Core Networks [3]. ERN-LUNG has 72 collaborating healthcare providers from 17 different European countries. Due to the lack of experts in the field of rare diseases, patients should benefit directly from expert knowledge, if they have a specific question regarding a rare respiratory disease. To provide the opportunity to address questions from patients and clinicians Europe-wide relating to any rare disease of the respiratory system to ERN-LUNG experts, the internet platform for an Expert Advisory Board (EXABO) was developed.

2. Methods

The concept of EXABO is based on the knowledge and experience with the former EU pilot project ECORN-CF², which is an online expert advisory board for Cystic Fibrosis. The key aspects of ECORN-CF were further developed and integrated into EXABO. While one area of rare respiratory diseases is covered in ECORN-CF, EXABO should be extended to all areas within ERN-LUNG. The experts must therefore be categorized based on their area of expertise and country. In each participating country, there is one expert group for each area of rare respiratory diseases. Each of these expert groups is organized by a moderator. The “superordinate moderator” takes on the task of organizing an area of rare diseases throughout Europe. In EXABO, the questions asked are distributed to the experts by moderators and the responses are monitored under quality aspects. Should an expert team not have the appropriate answer to a question, the superordinate moderator can reassign the question to the pool of Europe-wide experts [4].

Based on the stakeholder analysis and the concept, a prototype of EXABO was implemented. For the development of EXABO the waterfall model has been chosen. A two-staged testing process was used for testing. The results are significant for further development. In addition to the design and the technical realization of the Internet platform, the question-and-answer process, the internal communication between moderators and experts as well as the administration of the questions and users were of particular importance in the implementation of the prototype and the advancement to the present state. In the following the test phase is described and the improvements of the key features based on the evaluation of the test phase are highlighted.

2.1. Testing

The subject group, consisting of patients, relatives, physicians and programmers, was split up into the user roles questioner, moderator, superordinate moderator and administrator, so that a simultaneous interaction between them was possible.

²ecorn-cf.eu

In the quantitative test procedure, the subjects had to answer 30 questions regarding user friendliness, accessibility and navigation operating system based on a bipolar rating method using the four categories “do not agree”, “rather not agree”, “more likely agree” and “fully agree”. The neutral response option was excluded due to the fact that the test group for the EXABO prototype consisted of a very small number of persons.

The second stage was a qualitative test procedure, in which the subjects answered ten interview questions addressing improvement and weakness aspects.

2.2. Question-and-answer process

During the test phase, the question-and-answer process was tested for functionality and usability. The first step in the question-process in the prototype is selecting one of the eight rare and complex pulmonary conditions covered by ERN-LUNG: (1) ILD, (2) CF, (3) PCD, (4) PH, (5) nCF-BE, (6) AATD, (7) MSTO, (8) CLAD. In a next step, the questioner selects his desired language zone and inserts the question. The platform does not contain an automatic zone recognition, as it should be optional for the person using the EXABO platform to choose the language zone during travels. In the last step, personal data such as e-mail address, age, gender and country of residence are to be entered, whereby age and gender are not mandatory fields. For security reasons e-mail addresses are hidden even for logged-in users. The country of residence is essential for the assignment of questions as some languages are registered as official language in several countries. In consequence, a question that is asked in French will be sent either to a French or a Belgium group of experts, depending on the name of residency of the questioner.

The test phase has shown that a question cannot always be clearly assigned to a field of rare respiratory diseases in the beginning of the question-answering process. Above that, some questions may be so complex that it requires a different group of experts in the field of rare respiratory diseases. For this reason, the ninth Core Network “Other rare Lung Diseases” (ORLD) was set up. Furthermore, questions asked by a physician can be answered more specifically than those asked by laypersons, i.e. patients or their relatives.

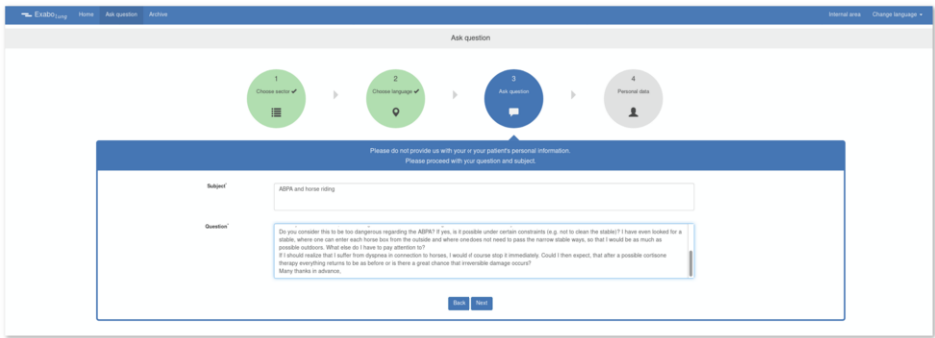

Figure 1. EXABO question entry mask.

After the questioning process, each question entered is automatically forwarded to the responsible moderator, who is the leader of his disease specific expert group and initiates the response process. The moderator assigns each incoming question to one of the ERN-LUNG experts in his group to either give the answer to the question or start

a discussion with other experts before publishing the response. However, questions can be returned by the expert if they are not fully answered. Returned questions are then translated to English and forwarded to the superordinate moderator, who will forward the question to the rare respiratory disease specific panel group across Europe, where the question can be discussed and the answer sent back to the respective moderator. When the answer is translated back in the source language, it can be published and archived on the internet platform.

During the test phase, it became apparent that a discussion with several experts is not only beneficial in the level of the superordinate moderator, but can also be initiated by the moderators in each expert group. Additionally, experts as well as moderators can comment on questions and answers and discuss the questions in a panel group of rare lung disease experts. In this context, the system provides date time for chat messages as well as a chat history, which enables the involved ERN-LUNG experts to retrieve their communication history. If the communication between an expert and the moderator involves additional experts and experts across Europe, the moderator may censor parts of the communication, i.e. if an expert has not fully answered a question and hence, returns it to the moderator. The reason for not having answered the question and other aspects can be set invisible by the moderator. However, the expert's commentary may already contain further approaches which are of advantage for other experts or discussion groups. In this case, the related moderator has the opportunity to censor the commentary instead of hiding the whole commentary.

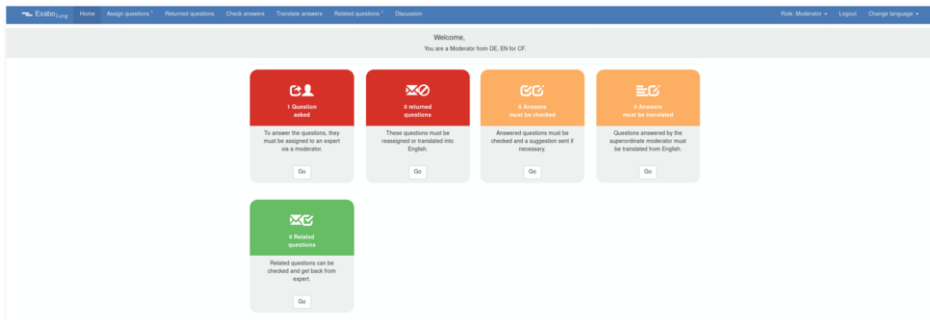

Figure 2. Moderator's welcome page with his jobs.

2.3. Administration of EXABO

An administrator manages the Internet platform and the user and role management. In the prototype implementation, the user interface of Keycloak [5] was used for the role and user management. The role distribution of EXABO is complex. In addition to experts, moderators and superordinate moderators, a user must also be assigned to a group of experts in a country with a specific field of expertise. Additionally, a user can be both an expert and a moderator, even for different fields of expertise or several countries. For example, a user can be an expert for cystic fibrosis and for primary ciliary dyskinesia, but is only the moderator for one of these fields. Accordingly, the responsible administrator who manages the user administration must work exactly to not forget or mix up a dependent role. If all roles are only listed without any structure, as is the case with the

prototype interface used, it will make it more difficult for the administrator to do his job correctly.

As an aid to the administrator, a completely new user interface with dependencies was programmed for the beta version. First, the actual role of expert, moderator, superordinate moderator and administrator is chosen, in the second step, the field of expertise is selected, whereby it is possible to make a multiple choice.

2.4. Technical realization

EXABO was implemented as a Spring Boot Java application and build with Maven. The front-end was realized with FreeMarker and Bootstrap [6]. The open-source single sign-on tool Keycloak [5] was used for the user and role management. The roles “experts”, “moderators” and “superordinate moderators” were included.

For the prototype a Web Application Resource (WAR) was used, so that an additional Tomcat server had to be installed on the server, in order to run the application. After the test phase and further development, it turned out that packaging with JAR and an integrated Tomcat server is the better choice for this application. The JAR is immediately executable.

3. Conclusion and Outlook

The generic aspect played a substantial role in the implementation of the EXABO Internet platform. As a result, new roles can easily be added in just a few steps and the platform can be enlarged for the implementation of other European Reference Networks.

The menu items are arranged in a logical manner, which makes the system user friendly and easy to use for laypersons as well as professionals. Translation into further European languages would allow a large number of other European citizens to enter their questions regarding rare lung diseases into the system and find more answers to their conditions. The internet platform is currently available in German and English in the beta version since March 2019 and is used by patients and care team members seeking advice on all aspects of rare respiratory diseases. The release of the full version is planned shortly. Special emphasis has been placed on a user-friendly interface/system/entry-points and an easy navigation operating system.

Integrating a Secure and Generic Mobile App for Patient Reported Outcome Acquisition into an EHR Infrastructure Based on FHIR Resources

Nico PLONER^{a,1} and Hans-Ulrich PROKOSCH^a

^a *Department of Medical Informatics, Biometrics and Epidemiology, Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Wetterkreuz 13, 91058 Erlangen, Germany*

Abstract. Both patients and physicians of the University Hospital of Erlangen would welcome means of digital data exchange between patients and the hospital. This work presents a system's architecture, FHIR based data model, security measures, and application flow based on patient's smartphones and a public cloud infrastructure to obtain patient reported outcome measures and merge that information with clinical routine data.

Keywords. Patient Reported Outcome Measures, FHIR, Mobile Applications

1. Introduction

Recent research revealed that both patients and physicians of the University Hospital Erlangen (UKER) would welcome means of digital data exchange between patients and the hospital [1]. Driven by the German eHealth law passed in 2015 [2] and encouraged by the growing research interest in patient reported outcome measures (PROM) [3-5], we developed the strategy for a digital patient connection into existing hospital IT infrastructures. For patients, the system relies on smartphone devices as a way of interacting with the hospital and their physicians. Information provided by the patient is pseudonymized, encrypted and stored in a public cloud infrastructure. From there it can be captured by a local application within the hospital's network, de-pseudonymized and then transmitted via FHIR interface to the hospital's electronic health record system (EHR).

Currently the system's purpose is to collect patient reported outcome measures, but it can easily be extended e.g. to allow patients to send other self-collected data (e.g. from wearable devices) to their physicians, or to enable physicians to send information to their patients while not being hospitalized. The hospital may specify definitions of care plans that describe at what point of time a patient is required to provide answers to a given questionnaire. Results are transmitted into the hospital's network and viewed by physicians.

¹ Corresponding Author, E-mail: nico.ploner@fau.de.

The objective of this paper is to describe the system’s generic data model, to illustrate the complete system architecture, including all security measures and to depict its use within a clinical scenario.

2. Methods

To enable a straightforward integration into existing systems, it was decided to use HL7’s Fast Healthcare Interoperability Resources (FHIR, [6]) as a data persistence and exchange format. First, the required subset of FHIR resources had to be identified and the corresponding data model had to be created. The smartphone application relies on this data model to its full extent. Participating hospitals may require a transformation into their proprietary data model when accessing patient data in the FHIR format provided by API interfaces.

Then, an architecture was created meeting the strong requirements of the German health care system regarding the exchange of patient-related data as well as granting access to any number of private smartphones without endangering the protected IT infrastructure of participating hospitals. This included the decisions on the location of the patient data storage, security measures to protect patient data against unauthorized access, mitigating the risk of leaked data, and providing access to participating hospitals in compliance with data protection regulations.

3. Results

3.1. The data model

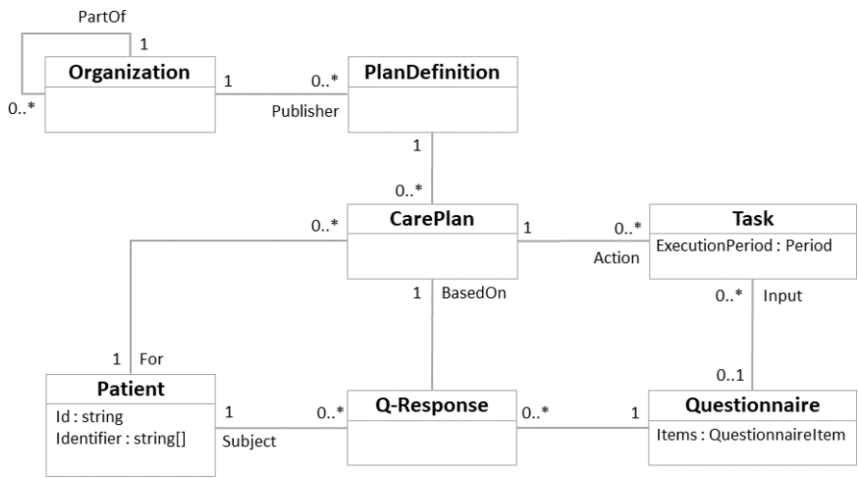

Figure 1. The system’s FHIR based data model

To facilitate interoperability, a subset of the standardized HL7 FHIR data model is used to store and exchange patient data. The seven FHIR resources utilized for this patient reported outcome application are linked together according to the data model illustrated in Figure 1.

Each participating department is represented by an "Organization" resource. Inner-hospital hierarchies can be mapped using the reflective relationship "PartOf". Each organization may publish one or more "PlanDefinition" resources which are used to define at what point of time a patient is requested to answer a questionnaire. Each patient is represented by a "Patient" resource with a unique Identifier ("Id", referred to as "Cloud ID"). A patient's pseudonym is stored in the "Patient" resource's "Identifier" collection. When an organization needs to collect data from a patient, a "CarePlan" resource is created that implements the specification of a particular "PlanDefinition" for that "Patient" and references all results. A "CarePlan" consists of multiple "Tasks", whereby a "Task" specifies at which point of time that patient needs to answer a given questionnaire. A "Questionnaire" resource consists of a list of questions to ask a patient and may serve as input to a "Task". A patient's answers to a given questionnaire are stored in a "QuestionnaireResponse" resource (abbreviated to "Q-Response" in Fig. 1) and subjected to the corresponding "Patient".

3.2. System Architecture

The entire system comprises of eleven components spread across four logical and three physical sites (see figure 2): The hospital's on-premise network infrastructure (A), a public cloud (B and C) and the patient's private smartphone (D).

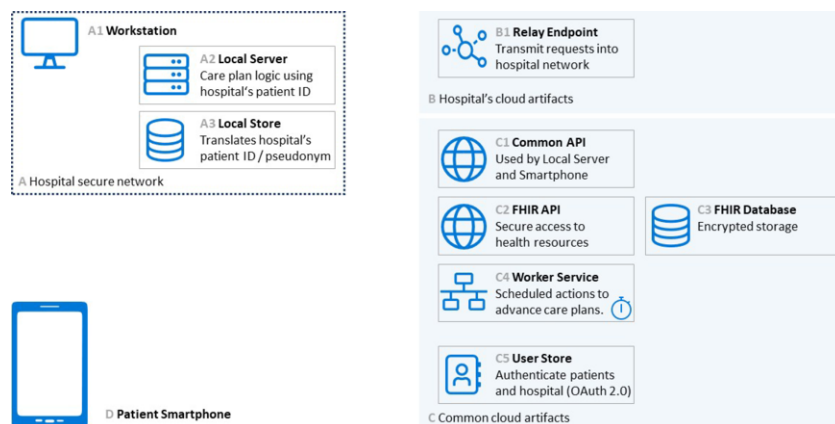

Figure 2. Integrating the patient app, the hospital's EHR and public cloud storage

Inside the hospital's secure network infrastructure (A) the system relies on the established workstations (A1) as user interfaces. Authenticated physicians may interact with the system to enroll patients into care plans and view patient reported results. Workstations connect to the system using a web server appliance (A2) hosted inside the hospital's network providing the patient's ID of the Hospital Information System. A local store (A3) is used for generating and managing unique pseudonyms for each patient. When communicating with the public cloud components (B and C) the localserver only uses that pseudonym, the patient's ID of the Hospital Information System is never transmitted outside the hospital.

No public endpoint into the hospital's network is exposed. The Local Server regularly polls the Relay Endpoint (B1) inside the public cloud for patients' responses to questionnaires.

In order to provide access to both, the hospital and its patients, a public cloud infrastructure is used. That infrastructure is located on German soil and run by a German provider subjected to the General Data Protection Regulation (GDPR)[7].

Common artifacts are services used by both, the Local Server (A2) hosted inside the hospital's network infrastructure and the patient's smartphone (D).

A common API (C1) provides functionality like creating a new patient record by the smartphone application (D), or requesting a one-time code for patient enrollment to be presented at the hospital's workstation by the Local Server (A2). Patient data is stored inside a FHIR database (C3) on an encrypted storage. A FHIR API (C2) provides secure access to the patients' data. A scheduled Worker Service (C4) regularly checks for updates in care plans and requests patients to answer questionnaires or transmits responses to the Relay Endpoint (B1). A cloud User Store (C5) and authentication service is used to secure communication between components and limit access to patients' data. Patients may interact with the system using their private smartphone device. A platform specific application is available in the usual app stores. The use of the respecting application does not require the patient to disclose identifying features such as name, email, or telephone number. It is also refrained from using device specific identifiers like IMEI, SSAID, MAC addresses/EUI, or Advertising-IDs. Instead, a random installation ID is created and used to create a new user in the User Store (C5) and a new patient resource in the FHIR Database (C3) after downloading the app.

3.3. Security

The following measures are taken to protect data and secure communication with and within the system:

- i. Data minimization: Patients using the smartphone application are not forced to disclose identifying information.
- ii. Pseudonymization: Information exchange between the components hosted inside the hospital's network relies on randomized pseudonyms preventing local identifier and cloud ID from being disclosed.
- iii. Short-term access codes: In order to enroll in a care plan, the patient enters a code displayed at the physician's workstation into the smartphone application. This code is valid for only a single enrollment within a short period of time.
- iv. Secure communication: For all communication between components, Transport Layer Security (TLS/SSL) is enforced.
- v. OAuth 2.0 for access: Access to a patient's data is restricted to their smartphone and to confidential clients (i.e. cloud components).
- vi. Encryption-at-rest: When saved to the FHIR Database, all data is encrypted so that even with theft of the data media no access is possible. All other cloud components hold decrypted data only in transient memory and never persist in health information.
- vii. Relay into hospital network: To deliver information into the on-premise hospital infrastructure, no public endpoint into the hospital's network is exposed. Using a polling mechanism, the local server reads data from the relay endpoint containing information to be transferred into the hospital.

3.4. Exemplary usage

The patient downloads and installs the application on his smartphone. After download, a random installation ID is created on that patient's smartphone. In the public cloud, a new "Patient" resource with a new Cloud ID is created and stored in the FHIR Database that may only be accessed by that patient's smartphone. The physician opens

the patient's health record in the EHR system and requests enrollment to a care plan. The EHR then requests a one-time code for enrollment from the Local Server providing the patient's ID. The Local Server either retrieves that patient's pseudonym from the Local Store or creates a new one. The Local Server then requests the one-time code from the Common API providing the pseudonym and an identifier for the care plan and passes the one-time code to the workstation for display.

The patient enters that one-time code into the smartphone application and chooses to enroll in this care plan. The smartphone application requests enrollment at the Common API, which creates the necessary resources in the FHIR database. Invoked by a schedule, the Worker Service determines, that this patient is required to answer a questionnaire and sends a push notification to the patient's smartphone. The patient then may provide answers in a given period of time. The results are stored in the FHIR Database. Invoked by a schedule, the Worker Service determines that the patient provided answers to a questionnaire. Using the Patient's pseudonym, the Worker Service posts a corresponding message to the hospital's Relay Endpoint. The Local Server polls the message from the Relay Endpoint, resolves the patient's ID in the Hospital Information System, stores the patient's answers and may notify the physician.

4. Conclusions

In this paper, we described a system relying on patients' smartphones and a public cloud infrastructure to create a digital connection into existing hospital IT infrastructures. An assessment by the data protection officer and the IT security officer at the University Hospital Erlangen already granted permission to use the system in studies using real patient data. We are currently planning initial research projects with departments at the University Hospital Erlangen in which the system is to be used and evaluated.

Interaction with Medical Venues in Megacities

María ÓSKARSDÓTTIR ^{a,1} and Anna Sigríður ÍSLIND ^a

^a*Department of Computer Science, Reykjavik University, Iceland*

Abstract. With the vast amounts of data that is being generated today, come new possibilities of understanding patient mobility. In this study, of urban mobility in ten mega cities worldwide, we try to understand the relationship between patients' environment and behaviour with regards to venues that provide some kind of medical care. We analyze longitudinal mobility data set from ten of the world's megacities and investigate urban dynamics and travel patterns in terms of interaction with medical centers. Our goal is to investigate universal patterns and gain an understanding of where people are coming from when they visit such venues and where they go afterwards as well how travel patterns progress throughout the day.

Keywords. Mobility, Health Data Science, Location Based Social Networks, Patient Behaviour

1. Introduction

Due to the global environmental changes and increased focus on sustainable living, there is a growing interest in understanding the movement patterns of people [1]. In line with that, the research on travel medicine and epidemiology has benefited from the increase of technologies such as location based social networks (LBSN) that enable geotagging as a new way of understanding mobility patterns and urban behaviour. The research on LBSN has been focused on understanding different aspects of mobility and user behavior [2,3,4]. Within that interest is mobility and user behaviour in relation to health purposes. Research has e.g. focused on geographic variation in well-being in Tweets [5] and exploring Twitter for medicine and health-related terms to find geographical patterns in symptoms control [6]. Furthermore, Foursquare data has been analysed to gain an understanding of the spatial distribution of ambulance incidents [7]. There is however still a gap in the literature regarding the understanding of how people interact with medical venues. In this paper we explore what people do before and after they visit a medical center, when their visits take place, and whether the mobility patterns are universal.

We analyze a longitudinal mobility data set from the location based social network service Foursquare, which has over 50 million active users monthly. We explore the movements of people between venues in the cities Chicago (CI), Istanbul (IS), Jakarta (JA), London (LO), Los Angeles (LA), New York (NY), Paris (PA), Seoul (SE), Singapore (SI) and Tokyo (TO). The mobility data set originates from Foursquare and was

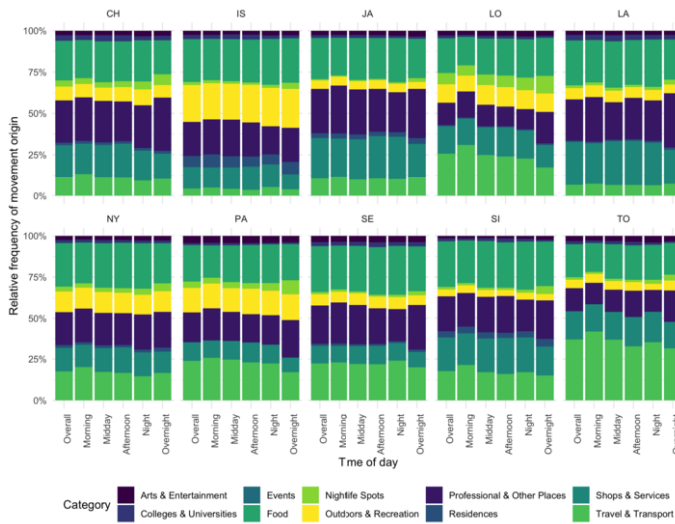

Figure 1. Relative frequency of categories of the origin of movements when destination is Medical Center

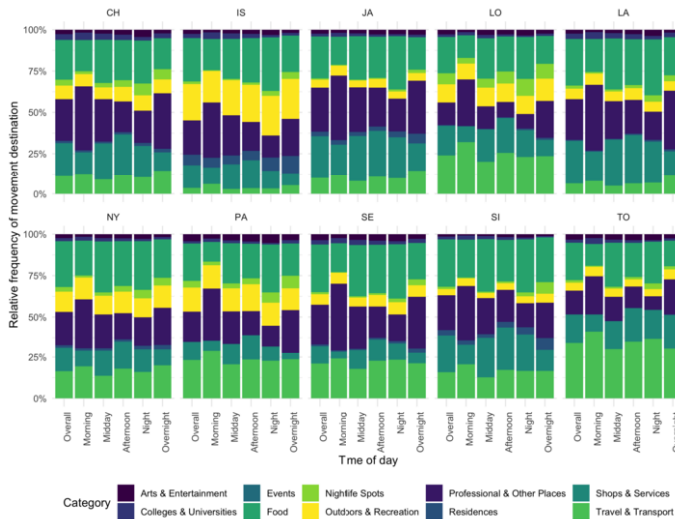

Figure 2. Relative frequency of categories of the destination of movements when origin is Medical Center

provided for the participants of the Future Cities data challenge² and spans two years. A movement is created in the data set each time a user checks-in at one of the city's venues and consists of two end points, the origin, where the user was last time they checked in and the destination where the user is currently checking in, as well as the part-of-day indicating the time of arrival at the destination, defined as morning (06-10), midday (10-15), afternoon (15-19), night (19-24) and overnight (00-06).

²See <https://www.futurecitieschallenge.com/>

Foursquare uses a hierarchical category set to categorise the venues on the platform. There are ten categories, as shown on the legend in Figure 1. Each category is separated into subcategories which are furthermore divided into subsubcategories. Medical Centers are for instance a subcategory within the category Professional & Other Places, and can be separated into subsubcategories such as Hospitals, Dentist's Offices and Physical Therapists. In total there are 923 categories³ on different levels where we, in this paper, focus on venues that belong to the subcategory Medical Centers.

2. Analysis of Movements

For our analyses, we inspect the data from two perspectives, namely where people are coming from when they visit medical venues and where they go to after their visits, by extracting all movements that end and start in a venue in the Medical Center subcategory, respectively. We look at the distribution of origin and destination venues on two levels of granularity, that is, category and subcategory.

Figure 1 shows the distribution of categories of the movement origins in the ten cities. In each subplot, there are six bars showing the distribution during various parts of the day. The first bar in each subplot shows the overall distribution, that is, irrespective of the time of day, where as the remaining five columns show, from left to right, the distribution in the morning, at midday, in the afternoon, at night and overnight. Evidently, this distribution varies from city to city, for example, venues in the category Outdoors & Recreation are more frequently visited in Istanbul than in Jakarta, and Travel & Transport venues are used more in Tokyo than in Chicago and Los Angeles. There is also a difference in patterns throughout the day. In London, for example, Travel & Transport venues have a higher frequency in the morning and in many cities the frequency of Nightlife Spots is the highest in the overnight period. The variation in venue categories is more prominent in Figure 2 which shows the distribution of to movements. Here, we can see that in many of the cities, Professional & Other Places are much more often travelled to from Medical Centers in the morning than overall, Food venues are less frequented in the morning and more at night.

Next we look at the venues travelled from and to at the more granular subcategory level. Based on Figures 1 and 2 we select the cities New York and Tokyo, because they show variety in their distribution of movements and they represent cities in different parts of the world. As there are over four hundred subcategories, we only look at the most frequented ones. Tables 1 and 3 show the highest ranked subcategories of venues of movement origins in New York and Tokyo at different parts of the day, respectively. Tables 2 and 4 show the same for the destination of movements. The first entry in each column is the most frequent subcategory during the respective part-of-day, and so on. The numbers in brackets show the ranking of the subcategory in the overall data set, that is, taking into account all movements. This gives an indication of the general frequency of the subcategories in the data set. These tables give some interesting insights into how people interact with Medical Centers within and between the two cities. First of all, Medical Centers appear very high in all the tables. This means that movements where both end points belong to Medical Centers are very common. This is probably due to people who are employed at these venues and therefore go there regularly and frequently check-in.

Secondly, Train and Metro Stations also appear very frequently. We already know that Travel & Transport venues are common in these two cities, and as with other venues, people use public transport when commuting to and from Medical Centers. Places for eating and buying food are also dominant in combination with Medical Centers. When comparing the two cities, we can highlight a few aspects. In New York, Pharmacies have a high ranking both before and after visiting a Medical Center. This is not the case in the other cities. We also see that venues that offer food and are not ranked high in general, appear in the list after visiting a Medical Center in New York, such as Fast Food

Restaurants and Donut Shops. In Tokyo, there is high correspondence between general travel patterns and those related to Medical Centers, as seen by the numbers in the brackets. Only Parks seem to be out of place here, as they are highly ranked before visiting a Medical Center.

3. Conclusion

Data from LBSN have the potential of revealing different patterns in human mobility. In this paper we draw from a study where we explore mobility patterns on what people do before and after their visit to a medical center, based on data from the LBSN Foursquare. We compared data from ten megacities and examined two megacities in more detail.

As the data set is from ten megacities, it should make the users rather homogeneous in the different cities. However, the different cities exhibit heterogeneous travel patterns where different categories of venues are dominant for each city. For instance, the sub-category of athletics and sports is absent in the Tokyo data but is frequent in the New York data. Another interesting finding is the lack of pharmacies. The New York data shows that pharmacies are visited both before and after visits to a medical center, which is not the case in the other cities. The different user behaviour can also be shown through apparent interaction with bridges and intersections in the Tokyo data set in general and with parks in relation to a visit to a medical center in particular. As the data comes from the same period of time, Foursquare as a LBSN looked and performed the same at all locations. However, the popularity in the different places and the stream of tourists that either use, or do not use LBSN, can vary in the ten megacities. Future work could both include understanding what the data represents in terms of the users of the LBSN, and to understand the patient patterns. Furthermore we want to examine the distance between the venues that show up in the data and explore the different ways geotagging is used in the ten megacities in relation to visits to medical centers and develop a measurement of the similarities between the geotagging of medical centers and overall categories.

Investigating the Barriers to Physician Adoption of an Artificial Intelligence-Based Decision Support System in Emergency Care: An Interpretative Qualitative Study

Cécile PETITGAND,^{a,b,1} Aude MOTULSKY^{a,c}, Jean-Louis DENIS^{a,c}, and Catherine RÉGIS^{b,a}

Abstract. The development of artificial intelligence (AI) systems to support diagnostic decision-making is rapidly expanding in health care. However, important challenges remain in executing algorithmic systems at the frontlines of clinical practice. Hence, most often, these systems have not been trained with local data nor do they fit with context-specific patterns of care. This research examines the implementation of an AI-based decision support system (DSS) in the emergency department of a large Academic Health Center (AHC) in Canada, focusing specifically on the question of end-user adoption. Based in an interpretative perspective, the study analyzes the perceptions of healthcare managers, AI developers, physicians and nurses on the DSS, so as to make sense of the main barriers to its adoption by emergency physicians. The study points to the importance of considering interconnections between technical, human and organizational factors to better grasp the unique challenges raised by AI systems in health care. It further emphasizes the need to investigate actors' perceptions of AI in order to develop strategies to adequately test and adapt AI systems, and ensure that they meet the needs of health professionals and patients. This research is particularly relevant at a time when considerable investments are being made to develop and deploy AI-based systems in health care. Empirically probing the conditions under which AI-based systems can effectively be integrated into processes and workflow is essential for maximizing the benefits these investments can bring to the organization and delivery of care.

Keywords. artificial intelligence, decision support system, emergency care, adoption

1. Introduction

The development of artificial intelligence (AI)-based systems to support clinical decision-making in health care is currently undergoing rapid expansion. AI, broadly

¹ Corresponding Author, Cécile Petitgand, Email: cecile.petitgand@umontreal.ca.

defined as the imitation of human cognition by a machine [1], is expected to enable better surveillance, detection and diagnosis of illnesses, as well as uncover novel treatments to spur precision medicine [2-4]. AI systems have already proven more effective than dermatologists at diagnosing skin cancer [5], and experts believe they will outperform medical specialists in surgery by 2050 [6]. As a result, health care is often presented as one of the most propitious domains in the upcoming "AI revolution" [7][8]. Yet, despite the enthusiasm around AI's capacity to increase the quality, safety and efficiency of care, important challenges remain in executing algorithmic systems at the frontlines of clinical practice. Hence, most often, these systems have not been trained with local data, nor do they fit with context-specific patterns of care [1][9][10].

The present research aims to explore some of these challenges by analyzing the implementation process of an AI-based decision support system (DSS) in the emergency department of a large Academic Health Center (AHC) in Canada. Research to date has identified several hurdles facing the deployment of AI systems in health care. These relate mainly to technical issues (e.g. lack of quality data sets to train algorithms; non-interoperable information platforms) and ethical/legal considerations (e.g. concerns about data privacy, algorithm opacity and patient safety; lack of ethical and legal frameworks to provide safeguards against inappropriate use) [11-14]. Research gaps remain in understanding how these barriers interrelate with human and organizational factors to drive and influence implementation.

This article adopts an interpretative perspective [15] to analyze the implementation of an AI-based DSS in an emergency department (ED), focusing on actors' representations of the system. We explore how health managers, AI developers, physicians and nurses perceive the AI-based DSS and interpret the interrelated technical, human and organizational barriers that lead to its ineffective adoption in the AHC.

2. Methodology

2.1. Study site and AI system

The study site is one of the largest AHCs in Canada, located in the province of Québec. In November 2018, an AI-based DSS was tested for implementation as a pilot project in the AHC's ED. The DSS is a diagnostic technology based on a deep-learning algorithm using clinical data and evidence-based results from the scientific literature. For patients visiting the ED, the DSS presents as a questionnaire that is answered on a mobile tablet. First, the patient is asked about the purpose of their visit to the ED. A Natural Language Processing engine then analyzes the text written by the patient to identify the chief complaint (e.g. skin rash, abdominal pain, etc.).

The patient is then asked a series of questions based on the chief complaint, with each question adapted to the previous response. The main objective is to identify red flags and signs of serious conditions. At the end, the DSS outputs a medical history that is printed by nurses or clerks and presented to the physician prior to their encounter with the patient. According to the DSS developers, who are also emergency physicians at the AHC, the medical history is meant to optimize patient questioning and diagnostic decision-making by providing physicians with information about the history of the presenting complaint, pertinent positives and negatives, past medical/surgical/family history, and social history.

2.2. Data collection and analysis strategies

An in-depth case study was performed at the ED, triangulating data collection methods and sources in an ethnographic approach to make sense of actors' perceptions of the DSS implementation process. A snowball technique was used to recruit participants and 20 semi-structured interviews were conducted: first with the DSS developers (5) and AHC managers (5), and then with emergency physicians (7) and nurses (3). Complementing the interviews (which were recorded and transcribed), informal conversations with nurses and clerks took place, as well as non-participant observations of meetings with managers, designers, physicians and nurses (10 in total), and of DSS utilization in context (15 hours). Field notes allowed observed situations to be contextualized, and preliminary elements of analysis to be identified. Finally, multiple secondary documents were gathered to better grasp actors' interpretations and trace the DSS implementation history; these included emails sent to physicians, documents prepared by AHC managers and developers, as well as different versions of the DSS-generated medical history. For data analysis, a description of the implementation process was first completed using a narrative strategy [16] that highlighted key timelines and activities. Then, using all collected data, thematic content analysis was performed with NVivo 12 software (QSR International) to identify, categorize and refine the main barriers to physician adoption of the DSS. [17]

3. Findings

Our analysis of the implementation process revealed several barriers identified by research participants that limited the DSS integration into clinical processes and workflow, and eventually drove several physicians towards non-adoption. These barriers related to three types of issue.

3.1. Availability

First, trials were conducted with patients to test whether they could complete the DSS questionnaire. Following adjustments to improve the intelligibility of the questionnaire, AHC managers and DSS developers jointly decided that only a subsection of patients would be asked to complete the questionnaire: English- or French-speaking outpatients who did not present any mental deficiency, visual handicap or alcohol/drug intoxication symptoms. This considerably limited the number of medical histories generated by the DSS.

Moreover, the lack of interoperability between the DSS and the AHC clinical information systems (Electronic Patient Record and Emergency Information System) meant that medical histories had to be printed and handed to physicians in paper form. These tasks were assigned to nurses and clerks who were already overworked with their regular obligations. As a result, medical histories were often not printed and thus were not provided to physicians. According to the DSS developers, this was the main factor limiting physician adoption of the medical history. Developers argued that physicians did not have enough opportunities to read medical histories and learn how to integrate them into their clinical practice. However, according to nurses, this did not really explain why physicians were not becoming "early AI adopters":

Every time it doesn't work, they say it's because nurses didn't print the history, or didn't direct them [patients] to the tablet, or because... "Wait a minute, you, [developers], what have you done to change our processes? What have you done to improve the medical history? What have you done to innovate?"[...] Since, it's something to help physicians, they need to play their part. (Nurse 2)

3.2. Usability

Some nurses were convinced that physicians were not using the medical histories because they had difficulty understanding patient information reported by the DSS. This was, in fact, a major barrier reported by several physicians. The physicians interviewed considered that the AI-based system was good at reporting simple complaints (a localized pain, a broken leg, etc.) but very poor at making sense of multi-complaint conditions (pain throughout the body, pain related to severe pre-existing conditions, etc.). This was a major concern, as most patients coming to the ED presented with the latter profile:

The history shows a multitude of symptoms to which the patient responded 'Yes, I have this'. But is it relevant? Is it active? Is it related to the current complaint? Afterwards, you need to disentangle all this. (Physician 4)

This type of feedback was directly reported to the DSS developers during focus groups. In response, adjustments were made to the design of the medical history to better classify patient information and simulate the clinical reasoning of physicians (presentation of pre-existing conditions, chief complaint, etc.). However, adoption rates did not increase significantly. Implementation data collected by the DSS developers showed that the proportion of annotated medical histories remained almost the same (around 30%) before and after these adjustments.

3.3. Perceived usefulness

At the start of implementation, several physicians were positively disposed toward using an AI-based DSS to enhance their diagnostic practice. However, some reported having discovered "errors" in the medical histories. In particular, two physicians reported that reading the medical history led them down the wrong diagnostic path. Had they not questioned the patient again, they would have made a serious clinical error:

But, you know, there are times when it completely took me down the wrong path... Not often... But it happened and it should not happen. It's like, me... I have zero tolerance. It's a tool that's supposed to help us... not at the price of losing a patient... But to miss something, something huge, you know... So that's... It didn't happen often. But it happened, so it cooled my enthusiasm. (Physician 6)

Perceptions of DSS-induced errors were shared among physicians, and this led some to develop a persistently sceptical attitude towards the usefulness of the DSS. The AI system was thus viewed as introducing a real risk into clinical practice that was capable of causing harm to patients. This is a perception that tends to increase clinician resistance to health information systems.

4. Discussion and implications

This in-depth case study shows how the combination of availability, usability and perceived usefulness can contribute to physician distrust of an AI-based DSS. The study further points to the importance of empirically probing the interconnections between technical, human and organizational factors to make sense of barriers that limit the implementation of AI-based systems in health care. However, these interconnections are rarely taken into account by researchers working on the deployment of AI-based technologies in clinical environments [4][9].

Moreover, the research emphasizes the need to consider the unique challenges raised by AI integration into clinical processes and workflow [10]. As shown in this study, actors' perceptions of a technology influence their actions towards it, be they related to adoption or resistance. For this reason, it is essential that managers responsible for implementation deal with specific assumptions and expectations regarding AI systems. Since these can generate negative perceptions (e.g. distrust in the effectiveness of automated decision making), that can hinder testing and adaptation, it is necessary to develop systematic learning processes based on user feedback to ensure that AI systems are implemented effectively.

Learning Interpretable Behavioral Engagement for Care Management

Subhro DAS^{a,1}, Chandramouli MADURI^b, Ching-Hua CHEN^b and

^aMIT-IBM Watson AI Lab, IBM Research, USA

^bIBM Thomas J. Watson Research Center, USA

Abstract. The health outcomes of high-need patients can be substantially influenced by the degree of patient engagement in their own care. The role of care managers (CMs) includes enrolling patients and keeping them sufficiently engaged in care programs, so that patients complete assigned goals leading to improvement in their health outcomes. Here, we present a data-driven behavioral engagement scoring (BES) pipeline that can compute the patients' engagement level with regards to their interest in: (1) enrolling into a relevant care program, and (2) completing program goals. This score is leveraged to predict a patient's propensity to respond to CMs' actions. Using real-world care management data, we show that the BES pipeline successfully predicts patient engagement and provides interpretable insights to CMs, using prototypical patient cases as a point of reference, without sacrificing prediction performance.

Keywords. Care management, personalization, metric learning, interpretability

1. Introduction

Care management is a patient-centered approach to population health that is “designed to assist patients and their support systems in managing medical conditions more effectively.” The Agency for Healthcare Research and Quality (AHRQ) recommends [1] that researchers should investigate (a) the benefit of care management services to different patient segments and (b) the parameters that affect modifiable risks. This can be especially important for those with chronic conditions and those who are transitioning to home care after being discharged from hospital [2].

While machine learning (ML) models may be helpful for patient segmentation and risk analysis, there is a desire for such models to be more explainable, or interpretable, so that they are more likely to be acted upon by human decision makers [3]. Recent reviews [4] have shown that a majority of studies in model interpretability are tied to the optimization of certain model properties for extracting explainable insights. While prior studies have attempted to identify risk stratification and disease progression parameters that affect modifiable clinical risks [5], to our knowledge, this is the first study that has proposed to learn engagement strategies directly from data, based on the quantifiable difference of patient engagement levels and segment-differentiating parameters that affect modifiable risk factors beyond those related to clinical risks.

This paper focuses on using ML methods to identify patient segments who are most likely to engage in care management, and on care manager (CM) decision support for explaining why they may or may not engage. While a few prior studies have measured patient engagement via quantitative surveys [6], no prior studies have successfully shown to measure patient engagement from real-world data. Its success will be critical for informing individual-level intervention decisions for care management [7].

2. Data

Care Management Records: The care management data, based on which we developed our method, are phone conversation logs of a private, not-for-profit network of community and specialty hospitals. It includes 4,504 transition of care and 440 chronic care related interactions of 3693 unique patients over a 22-month period (Dec-2015 to Oct-2017). From each patient’s anonymized (by Mongo Patient ID) engagement interaction history, we extracted 53 features that includes: (a) basic demographic information (e.g., age, gender); (b) patient’s care program context (e.g., program experience, whether the patient is enrolled, number of days in the program etc); and, (c) interactional context between CMs and patients (e.g., the day of the week when the recorded call occurred). Using this data, we aim to introduce a data-driven approach to achieve two crucial tasks for decision support: program enrollment (“ENROLL”) and goal attainment (“GOAL”). The ENROLL dataset captures the enrollment status for the two assigned care programs: “Transition” include those transitioning from hospital to home after being discharged, and “Involve” include those involving with chronic disease (diabetes etc.) management.

The GOAL dataset, composed of 28 different goals, is classified into six focus areas based on their similarity: Educational (e.g., demonstrate understanding of post discharge, diabetes education), Implementation (e.g., adequate functional, transportation, support for healthy coping), Medications (e.g., adhere with medication regimen), Reducing Risks (e.g., resolve care gaps), Self Care (e.g., understand the benefits of being physically active & healthy diet needs), and Other (e.g., effective care transition). Table 1 summarizes the goal attainment rate for each goal focus area, i.e., the ratio of the number of goals recorded as ‘met’ to the total number of goals in each focus area. The interventions of each goal area are grouped into seven categories: Referral (e.g., refer to a nutritionist for diabetes nutrition education), Education (e.g., educate patients on the importance of physical activity), Coordination (e.g., follow up with providers on refills), Screening (e.g., assess breathing symptoms), Coaching (e.g., provide a log for side effect recording), and Other (e.g., follow up with provider treatment).

3. Methods: Behavioral Engagement Scoring Pipeline

To further incorporate the data-driven approach for indicating patient engagement level and producing interpretable insights, in this paper, we introduce the Behavioral Engagement Scoring (BES) pipeline, which is composed of three components:

3.a) Engagement Outcome-driven Distance Learning: This component aims to learn an engagement outcome-driven distance metric so as to project patient feature-based vectors onto a subspace wherein patients with similar outcomes are closer to each other. Such metrics would be essential to ensure those with opposite outcomes are far away from each other. Here, we adapt Locally Supervised Metric Learner (LSML) [8], which helps estimate the outcome-adjusted distances among patients in the newly transformed vector subspace. The patient features are represented as $X \in \Omega$, where Ω is the vector space, and the class labels as $Y \in \{0, 1\}$. For program enrollment, $y = 1$, if the status is "Enrolled" or "Completed", and, $y = 0$, if the status is "DidNotEnroll" or "Disenrolled". Similarly, for goal attainment, $y = 1$, if the status is "Met", and, $y = 0$, otherwise.

We minimize the generalized Mahalanobis distance across all CM records segmented into homogeneous (records with same outcome) and heterogeneous (records with opposite outcomes) neighborhoods. The feature transformation matrix that minimizes this generalized Mahalanobis distance, renders the data into the desired space, where records with similar outcomes are compact and those with opposite outcomes are distant. Refer to [8] for the complete LSML algorithm that derives this feature transformation matrix. We employ this matrix to obtain the projected feature set. For the rest of the pipeline, we leverage these outcome-adjusted projected features and the corresponding Mahalanobis distance between patient-based vectors to learn patient segments and to estimate each patient's propensity to engage with CMs.

3.b) Learning Patient Segment-based Behavioral Profiles: This component aims to capture patient segments wherein patients and CMs interact with a similar behavioral profile. However, the optimal number of patient segments is not known "a priori". With that objective and constraint in mind, hierarchical clustering [9] is employed to identify patient segments based on the outcome-adjusted distances in the newly projected vector subspace and to learn the key factors that drive differential engagement outcomes. We choose Complete Linkage method (as it has highest outcome-differentiation power, measured by ANOVA scores) to compute inter-segment similarity of the furthest pairs.

To compute the optimal number of segments, Elbow method (an automatic tuning algorithm) tracks the acceleration of distance growth among segments and thresholds the agglomeration at the point where the acceleration is the highest. Hence, our population is clustered into k segments, each capturing distinctive patterns that drive differential patient responses in engagement. We further identify prototypical patient cases in each segment to serve as examples to showcase the distinctive patterns in their behavioral profile and to add interpretability to the engagement scores produced by the BES pipeline. The prototypical patient cases are those with positive engagement outcome, i.e., $y = 1$, while being closest to the centroid of each patient segment in the transformed feature space.

3.c) Estimating propensity to respond: In this component, we train a Generalized Linear Model (GLM) to compute the engagement score for patients who have been assigned a program to enroll or a goal to attain, using the behavioral segment information found in 3.b. The GLM feature weights for each segment k are computed by minimizing the least squared errors over all the data points from that segment k . This trained GLM with optimized feature weights is used to compute the scores for new patients, which represents their propensity to respond to CM's engagement calls or intervention assignments for goal completion. The last stage of our pipeline contains a Support Vector Machine (SVM) to classify the potential engagement outcome of each patient using their BES.

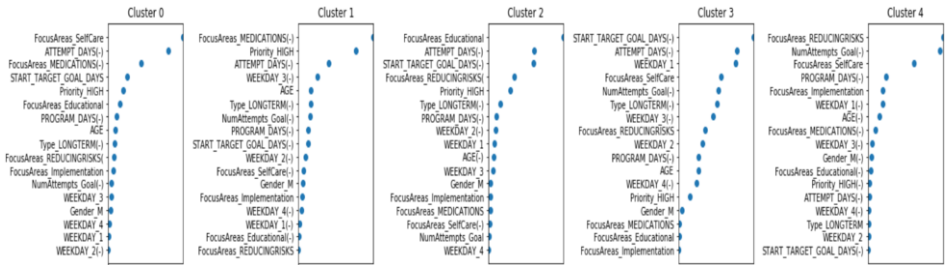

Fig. 1. Feature weights indicating patient response driver across 5 behavioral segments for goal attainment.

4. Results & Discussion

The BES pipeline, introduced in this paper, segments patients based on not only the patterns exhibited during patient-CM interactions, but also their engagement outcomes. Although each feature contains only weak signals to differentiate overall engagement outcomes, when considered collectively in a segment, the combined feature sets can explain rich engagement behaviors for care planning.

Performance evaluation on engagement outcome prediction: The predicted engagement outcome of each patient task is compared with what actually happened as indicated in the CM transaction records. The results across all patient tasks are aggregated to evaluate the overall performance of the BES pipeline on engagement outcome prediction in terms of precision, recall, accuracy and F1-score. In particular, the evaluation aims to compare the following three versions. The first “Population-based (Baseline)” directly trains a SVM classifier in the BES pipeline using all the population data without differentiating patient segments. The second “Behavioral Profile-Driven” trains BES for each of the patient segments using data belonging to patients in that segment. The third “Prototypical User-Driven” trains BES using only prototypical patient cases in each segment. Table 2 shows the performance evaluated with 5-fold cross validation, indicating that the BES pipeline helps predict patient responses (“whether to engage”) for each type of engagement tasks with high precision (> 90%). This implies a high percentage of successful engagements if BES-based recommendations are followed for task prioritization.

Drivers of Differential Patient Response: We analyze feature weights of the model trained for each of the five patient segments in order to pinpoint drivers that contribute the most to its engagement outcome prediction. The results are used to provide support for CMs to understand the rationale of the predictions. Fig 1 demonstrates that feature rankings are significantly different when the population-level feature rankings are compared with the segment-based ones (Spearman’s coefficient ρ ; $p < 0.01$). In some segments,

Table 2. Performance with 5-fold cross-validation.

Method	Performance Metrics	Program Enrollment: Involve	Program Enrollment: Involve	Goal Attainment
Population Based (BASELINE)	Accuracy	0.96	0.96	0.89
	Precision	0.95	0.94	0.93
	Recall	0.99	1	0.95
	F1	0.97	0.97	0.94
Behavior Profile-Driven	Accuracy	0.93	0.74	0.79
	Precision	0.95	0.94	0.92
	Recall	0.96	0.65	0.83
	F1	0.95	0.76	0.87
Prototypical User-Driven	Accuracy	0.93	0.74	0.95
	Precision	0.95	0.93	0.99
	Recall	0.96	0.65	0.96
	F1	0.95	0.76	0.97

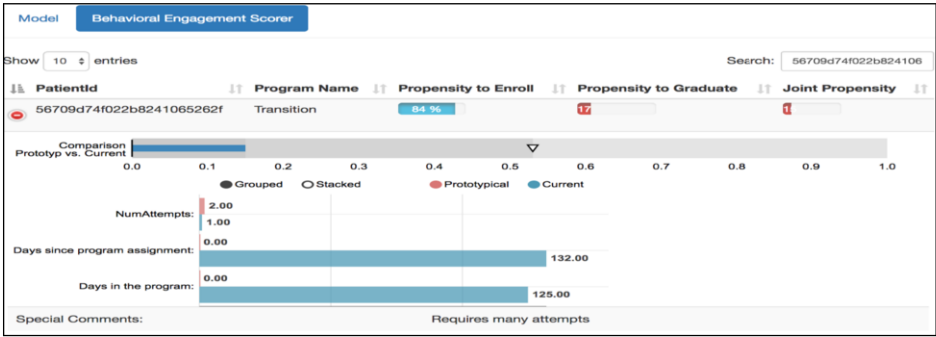

Fig. 2. Interpretable engagement insights for Care Managers for shared decision making.

we observe strong indicators of CM influence (e.g., how long a CM has been trying to help the target patient obtain his/her goal, how many calls have been attempted before the goal attainment status is determined). In other patient segments, we observe certain goals as more likely to yield positive engagement responses.

Interface and API for Shared Decision Making: We developed a web-based user interface that provides the CMs access to explainable insights about the gauged engagement level, the predicted response and the prototypical patient cases. Fig 2 shows the interactive tooling based on a demo API customized for CMs to make their decisions before the call regarding which patients to call first for program enrollment and for goal attainment, and what are the reasons that they might or might not be engaged.

5. Conclusion

The main contributions are: (1) developing a quantitative and personalized approach for identifying patients who are more likely to engage in care management; (2) demonstrating empirically, using real-world data, that our approach provides more accurate engagement outcome predictions compared to a “one-size-fits-all” population-based approach; (3) generating explainable insights on each patient’s behavioral profile from the prototypical patient cases within his/her segment. Performance evaluation results show that, in our case, explainability does not come at the expense of model performance.

Abstract. The Ministry of Health (MoH) stated the National Digital Health Strategy 2018-2024 in order to establish the conceptual guidelines for the design and development of interoperable health information systems. It included the creation of a National Digital Health Network, and a Citizen Health Portal to inform and empower patients about their rights. For instance, the Digital Vaccination Card is already available and has equal legal validity as its paper version. The platform also works as a personal privacy manager, to configure the consent for Health Information Exchange through the network, or to check the access logs. This paper outlines the implementation experience of this powerful tool at a national level.

Keywords. eHealth, Personal Health Records, Health Information Exchange, Privacy.

1. Introduction

The development of sustainable Health Systems that promote universal access to care can only be enabled by the appropriate use of digital technologies[1]. According to the Argentine legislation, the medical record can be paper or magnetic supported, and should always be subjected to the principles of integrity, uniqueness, inviolability and confidentiality. There is a legal obligation for the health institutions "...upon request of the patient, owner of the medical record, an authenticated copy must be provided, within a period of forty-eight hours from request...".

Argentina has a complex federal, segmented and highly fragmented healthcare system, which also translates into the generation of information silos. In many health centres around the country, health records are still kept in manual registries and logbooks. In a preliminary survey for the public sector, at least 80% of the healthcare facilities had no computers or internet connection. Therefore, patient's right to access their own information is frequently hard to accomplish.

During the previous 15 years several management systems were implemented at the Ministry of Health (MoH) for the Essential Public Health Functions. Most of them

were independent collecting tools that required paper form fulfilment for later electronic transcription, fuelling the administrative burden. Nevertheless, these systems empowered the MoH with important information for decision making: Surveillance, Immunization, Vital Statistics, Disease Registries, Public Health Insurances, among others. Most of this information is not available to general practitioners or patients themselves.

The Argentinian National Digital Health Strategy 2018-2024[2] has the vision of reducing quality gaps in health care, implementing information systems that identify the characteristics and needs of the population, allowing longitudinal and comprehensive monitoring of people throughout the entire health system and providing innovative tools to health professionals and patients. It encourages every healthcare institution in the country to progressively adopt any interoperable electronic health record (EHR) system. The National Digital Health Network was launched in April 2019, using an enterprise service bus technological infrastructure to connect different systems across the country. The data remains in each information system repository, and is only communicated to other domains if necessary (e.g. when the patient visit another clinic), and the citizen has given his consent for Health Information Exchange.

A Personal Health Record (PHR) has been defined as a set of computer-based tools that allow people to access and coordinate their lifelong health information and make appropriate parts of it available to those who need it. They usually consist of provider-tethered applications that allow patients to electronically access health information documented and managed by a healthcare institution. Although patient portals are already being implemented, it is still unclear in which ways these technologies can influence patient care[3]. In digitally advanced countries like Estonia, every person has a personal account in a patient portal, where they can review all their healthcare data and insurance expenses[4]. My Health Record is Australia's electronic PHR system, which from 2012 to 2017 got 21% of registered population. There were low levels of awareness and concerns about sharing records and equity of access for all Australians[5]. The government changed patient enrolment from opt in to opt out, reaching 90% of the population by 2019. There are not many international examples of Vaccination eCards, despite it seems there would be many benefits with its implementation[6].

In 2017 the Argentinian Ministry of Modernisation (MoM) jointly with the MoH launched a Citizen Digital Health Portal (*Mi Argentina / Mi Salud*) for personal access, empowering the people and recognizing their pivotal role in their own health. This paper describes the implementation of the Citizen Health Portal in Argentina.

2. Materials and Methods

2.1. Setting

Argentina is a large country of more than 1 million square miles located in the southern half of South America. Its population is around 45 million people. The sovereign state is a Federal Republic subdivided into twenty-three provinces and one autonomous city. Beyond the recurrent economic crises, it is an upper middle-income country, and has a developed healthcare system. It has a quite complex organisation, with 3 subsystems: Public Care, Social Security and Private Insurances. Many of its shortcomings come from its segmented and highly fragmented nature. Since 2018, the MoH has embraced

an action plan to implement a public health reform to provide actual Universal Health Coverage (UHC) by strengthening provincial health systems[7].

Digital Health is one of the three pillars for the effective implementation of UHC. Through Resolution 189/2018, the highest health authority in Argentina settled the way forward to build, in collaboration with provincial governments and referents of the 3 subsystems, a network of information systems focused both on the population and individual health of each patient.

2.2. Methods

The Citizen Digital Health Portal was designed and developed following the user centered design and accessibility rules promoted by the MoM[8]. People should be able to access their health data in an easy and comprehensive way[9]. Usability was tested, but it is not in the scope of this paper. The different modules of *Mi Argentina* -the Citizen Digital Platform- are described, including *Mi Salud*, the health section. We assessed its utilisation with quantitative aggregated and de-identified measurements of different services provided by this tool.

3. Results

The Citizen Digital Health Portal *Mi Salud* is the health section of *Mi Argentina*[10], the digital public service delivery platform developed by the MoM. In 2017 the Argentinean Government unified the official landing website in the Argentina.gob.ar domain. These two platforms are crucial milestones in terms of digital service delivery in the country. Important work has been undertaken, following the example of the United Kingdom (gov.uk), and other OECD members and partner countries in the region like Mexico (gob.mx) and Peru (gob.pe)[11]. As a result, the government-citizen relationship builds on the use of Argentina.gob.ar website and *Mi Argentina* platform. Both were designed and implemented by the Service Delivery Team within the MoM. Unique personal identification, privacy and security were undertaken by different modalities of accreditation, the highest one requiring biometric validation. Since its deployment in 2017, the number of users has been constantly growing. As of October 2019, more than 2.3 million users had registered on *Mi Argentina*. A line chart with the number of active accounts can be seen in Figure 1.

Figure 1. Line chart showing the number of *Mi Argentina* accounts during the last 2 years.

To gain full access to *Mi Argentina*, each citizen must create an account and validate her digital identity through biometric technology. Although this strategy potentially reaches the entire population, it was initially available for citizens over 13 years old who could individually open an account in *Mi Argentina*. Children will be included soon, with special permission from their parents or tutors.

Mi Argentina provides appointment booking (*Turnos*) for government services like immunization and online certifications from the National Administration of Social Services (ANSES) and other offices. There is a Wallet (*Mi Billetera*) where users can access their national identity eCard, driving licences, car documents and insurances, and other digital certificates in one place. *Mi Argentina* can be accessed both web and through mobile application. Screenshots of the App can be seen in Figure 2.

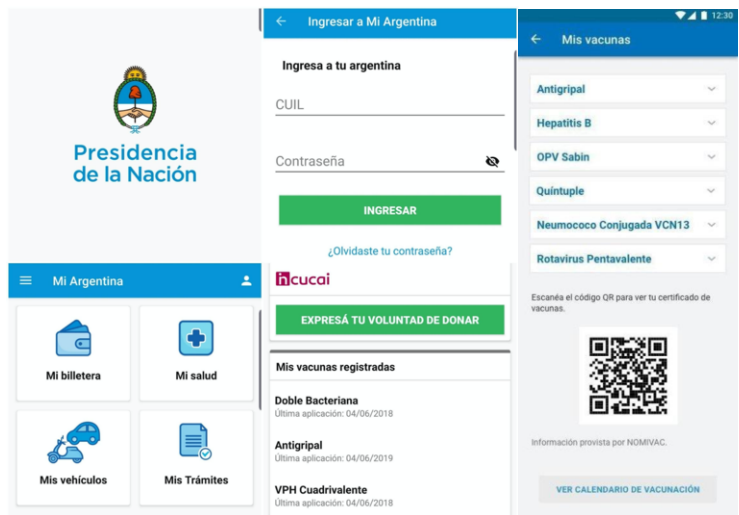

Figure 2. Screenshots of *Mi Argentina* App and *Mi Salud*, the Citizen Digital Health Portal.

The Health Section (*Mi Salud*) includes different services for citizens: a map with the location of healthcare centres, institutions that perform free HIV test, online consent for organ donation will, online access to health formalities like getting the unique disability certificate, and information about the current healthcare coverage. One of the most important milestones was the Health Information Exchange (HIE) consent. The portal itself is a domain of the Digital Health Network. It works as a personal privacy manager, to set the consent for information exchange through the network. Patients can also check the EHR access logs. Up to December 2019, there have been almost 41,000 citizens (73% male) who have set their consents, with 94% of affirmative responses, as seen in Table 1. Even though it could be seen as a low enrolment rate, HIE is based on an opt-out modality.

Table 1. Data regarding patient utilization of the Digital Health Network and the Citizen Portal.

Number of Citizens (2019)	44,938,712
with an EHR linked to the Digital Health Network	2,068,448
with an active <i>Mi Argentina</i> account	2,375,949
with a validated <i>Mi Argentina</i> account (biometric)	922,480
with active consents for Health Information Exchange	40,940 (94% affirmative)

Recently, we implemented in *Mi Argentina* the Unified Digital Vaccination eCard. It is digitally signed and has a QR validation code that gives the same legal validity as the usual cardboard immunization card issued by health institutions. Through the citizen digital platform *Mi Argentina* people can individually see their registered vaccines. There are almost 30,000 daily accesses to the eCard. Patients can report if there is missing data in the digital card. This eCard is built using the data from the Federal Registry of Nominalized Vaccination (NOMIVAC)[12]. NOMIVAC is a module of the Argentinian Public Health Information Management System (SISA) that collects the vaccination data of every citizen in the country. There are more than 52 million registered doses. This module allows any vaccinator to register the applied doses in real time, through the web or a mobile application that even works offline. It also gets data from local systems through interoperable web services, mainly from public centres but progressively also from social security and private healthcare institutions.

4. Conclusion

Even though single institution PHR might not change the traditional passive patient role, we strongly believe that our National Digital Health Portal has the potential of empowering citizens. It allows patients to access their information and change their HIE consent for the National Digital Health Network. The progressive addition of new tools within *Mi Argentina* (Vaccination eCard and soon International Patient Summary, Lab results, ePrescriptions) would enhance such vision. Further analysis of the platform utilisation is needed. Improved promotion and support might lead to higher citizen engagement with *Mi Salud*, especially for populations at risk of digital exclusion.

Abstract. Collecting accurate food consumption data is challenging for nutrition practitioners. Mobile devices are interesting alternatives to traditional ways of collecting assessments by reducing burden of use. Our objective was to develop and evaluate a mobile application for food intake documentation, targeting particularly the parents of pediatric patients. NutriKids is an application designed to guide users step by step in their assessment by asking relevant questions and taking advantage of the camera function. The quality of nutritional assessment using NutriKids was evaluated through the analysis of food diaries completed during two days under real-life conditions (home use). NutriKids demonstrated to provide satisfying degree of quality in 84% of the reported items. A detailed analysis of quality components highlighted that NutriKids interface could be improved for quantitative estimation and for specific information on added fat or sugar. Besides, a feedback survey highlighted the high acceptability of the application by the participants. These findings demonstrate the potential of this guided approach application. With further development of NutriKids and controlled based assessment with larger populations, we hypothesize that our results would reach statistical significance in all aspects of nutritional assessment quality.

Keywords. mHealth, mobile applications, nutrition assessment, diet records, child

1. Introduction

In the pediatric setting, dietary assessments are required in a wide range of medical conditions, such as children with weight problems, gastrointestinal disorders, metabolic or endocrine disorders, etc. Collecting accurate food and beverage consumption data from patients is challenging for nutrition practitioners. Thus far, three methods have mainly been used: Food Frequency Questionnaires (FFQ), 24H Dietary Recalls (24HR) and Food Records [1]. These methods usually require parents to write down precisely everything eaten and drunk during a few days, using different means such as

¹ Mrs. Lea Jacques, Geneva University, Faculty of Medicine; E-mail: lea.jacques@etu.unige.ch

questionnaires or paper journals in the form of a blank table. This task requires personal investment and time. Moreover, traditional paper tools are hampered by practical limitations, which generate burden for the user and thus challenges the cooperation between user and practitioner.

With digitalization, new dietary assessment methods are developing rapidly. Comparative studies have already demonstrated the positive impact of digital technologies over traditional paper-based methods by increasing participation rates and reducing the burden of use [2]. However, evidence validating their efficiency is still lacking and the accuracy of collected data, namely precise description and quantitative estimation of the reported food, remains a critical point.

Digital tools to quantify food servings have greatly evolved over time. Early versions help users by displaying different serving sizes pictures. Studies have demonstrated that these tools were associated with lower precision compared to weighing [3], although they increased accuracy of intake estimation when no scale is available [4]. Other techniques rely on photographs taken by the user which are then analyzed by dietitians. However, in studies evaluating dietitians' proficiency to estimate dietary intake based on digital food images (pictures of meals), it appears that the quantification accuracy is quite low without specific training for this task [5,6]. More recently, new approaches relying on artificial intelligence, featuring automatic food identification and portion size estimation are under development (e.g. NutriNet, Snap-n-Eat). Regarding the precision of food description, studies have shown that long exhaustive lists of food items based on food databases don't improve quality. Overall, existing tools still suffer from suboptimal reliability, and tools based on guided approach may represent a promising improvement.

1.1. NutriKids

We developed a new mobile application, NutriKids, in partnership with a group of experts in paediatric dietetics at the Geneva Children's Hospital. NutriKids is meant to offer a smartphone alternative to actual paper journals (food record method). The creation process started by analyzing recent nutritional assessments to identify which information should be collected. It highlighted the importance of three elements for assessing valuable dietary intake, namely description, quantity and information on added fat/sugar. From there, we designed our application. The aim was to guide parents in the assessment process in order to minimize the omission of key information previously identified. For example, no food item can be registered if its quantity hasn't been indicated. More specifically, for every food item potentially cooked or seasoned with fat, the application automatically asks the user about the amount of added fat (see fig. 1). A camera function is also provided to capture food labels or product specificities, reducing the burden of writing down descriptions. Besides, we set up a system of « typical meals »: when the users select the main food item they wish to report, other items, expected to be associated with the main one, are automatically proposed (see fig. 1). We decided to avoid long exhaustive lists of food items that users can select. Instead, we preferred short lists containing frequently selected items and added the possibility for the user to write down his own description or to take pictures of the product. These particularities differentiate NutriKids from the numerous existing applications that we have tested on the market (e.g. Gluci-Check, MealLogger, SHYE, Food(lg), FatSecret, iEatWell), which are already very useful for some functions but lack the guiding aspect in data collection.

After the implementation of the first version, we performed an expert evaluation using the Nielsen criteria [7] and modified few elements to enhance the application's coherence and efficiency of use.

A usability test, performed by a distinct group of 10 users with the application's final version, confirmed that users don't encounter major difficulties using the application.

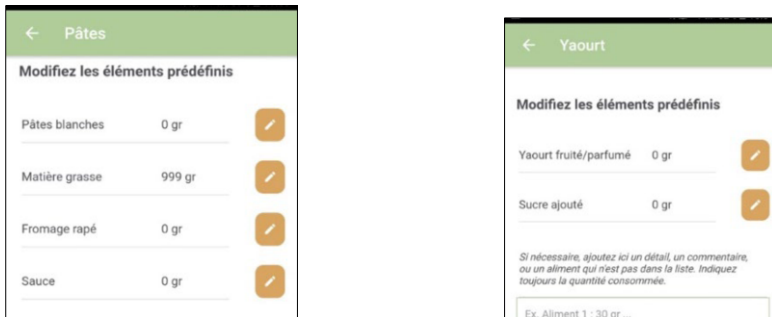

Figure 1. Screenshots of NutriKids' interface displaying the "typical meal" structure as well as the automatic recall for fat/sugar quantity

Following the creation of the application, we evaluated NutriKids during a two-day assessment period in a pediatric setting. This period of time was set to be very close to the current conditions of dietary assessment at the hospital (3 days), to avoid bias of motivation.

2. Method

2.1. Evaluation

We performed a critical evaluation of the quality of the data reported by a group of 12 participants during a dietary assessment. Participants included parents from pediatric patients requiring a nutritional assessment or having completed such an assessment in the past two years, as well as volunteering parents from the local community.

Participants were requested to report all food and beverage intake within a period of two days using NutriKids. Once collected and anonymized by the investigator, data were then analyzed by hospital dietitians according to the criteria identified as being essential for a valuable dietary assessment:

- Information about added fat and/or sugar (if relevant)
- Detailed description of ingredients and/or picture of food brand
- Precise weight (given in gr., ml., tsp. or Tbsp.) or picture of the portion

For every food or drink item reported during the two-day evaluation period, each criterion was evaluated by a dietitian as « sufficient » or « insufficient », depending on whether additional information was required or not in order to evaluate properly the nutritional content of the meal. Thus, on the two-day period, we calculated for each criterion (description, quantity and added fat/sugar) the percentage of items reported correctly: 0% being no reporting deemed sufficient at all and 100% being perfect reporting for all items. Each criterion had identical ponderation for the evaluation of the

global quality (primary outcome), which was calculated as the mean of the three criteria.

We calculated the group results as the mean of participants' individual score.

To limit assessment biases, a second evaluator independently controlled 10% of the data and found no significant discordance (kappa analysis > 0.8).

At the end of the evaluation period, participants also had to complete a survey containing Likert based questions, as well as open questions providing a more qualitative evaluation of the application.

3. Results

3.1. Evaluation of NutriKids

All 12 participants were women, mostly aged between 35 and 45 years and from higher educational levels. 88% of them were familiar with smartphone use. 55% had medical reasons to participate, 44% volunteered.

The total number of food and drink items reported for all 12 participants was 193, among which 69 needed information about added fat or sugar. As shown in table 1, mean global reporting quality was rated as 83.80%. Quality was specifically considered as "sufficient" for descriptions in 95.52%, for quantitative estimation in 88.20% and for added fat/sugar information in 67.68%.

Table 1. Mean quality of the assessment for each criterion

	n	Mean (%) ± SD
Global quality		83.80 ± 15.66
Food description	185 (N=193)	95.52 ± 6.86
Quantitative estimation	173 (N=193)	88.20 ± 14.62
Added fat/sugar information	50 (N=69)	67.68% ± 33.95

3.2. Feedback evaluation form

Participants rated the general ease of use of NutriKids 7.4/10 and its intuitiveness 8.9/10. The major difficulties reported were about finding desired food items in the lists and informing about food's quantity, especially when done without using a scale or when the meal was complex. The majority of the participants used the camera function and reported it to be very useful.

Interesting improvement suggestions concerned the possibility to add notes with recipes, or the possibility to create a personal list of specific items to reuse, avoiding the burden of copying all information again if often consumed.

4. Conclusion

The evaluation of NutriKids confirms previous findings that mobile applications may represent a valid alternative to traditional paper-based methods. The quality of intake assessment was globally good, and participants were mostly satisfied with NutriKids.

Separate analysis of each quality criterion underscores which aspects cause difficulties to participants and could benefit from further improvement. Precise

description of food does not appear to be a problem given that more than 90% of the items are evaluated as sufficiently well described. Difficulties were mostly encountered for quantitative estimation, especially when no scale is at hand. Possible improvements include image-assisted tools such as a food atlas (ranges of food photographs displaying different serving sizes with associated quantities) or machine learning (real-time analysis for automatic food recognition and weight estimation). However, even though machine learning has demonstrated its potential in improving quantitative estimation and reducing underreported food [8,9], it may require a certain time before being used out of the lab and may not solve the problem of complex meals with mixed ingredients.

Concerning information on added fat or sugar, our fairly good results for this specific aspect of food reporting strengthen our hypothesis that a guided approach represents a valuable tool to improve the quality of nutritional assessments. To our knowledge, no other study has addressed the issue of a guided approach up to now.

4.1. Improvements, Perspective

NutriKids' interface could be improved to guide even more the food collecting process. Users could, for instance, be constrained to inform about added fat or more clearly invited to provide pictures. Additional research should be undertaken to find the best solution for quantitative estimation when no scale is available. No clear solution has yet been found to achieve this error prone task, but a combination of different image-assisted methods could be sufficient for daily practice. With those few adjustments, we hope to provide a valid alternative to the traditional paper journal.

On Patient Accessible Electronic Health Records and the Experienced Effect on the Work Environment of Nurses

Jonas MOLL ^{a,1} and Åsa CAJANDER ^b

^a Centre for empirical research on information systems, Örebro University, Sweden

^b Department of Information Technology, Uppsala University, Sweden

Abstract. The work environment for nurses is challenging, and even though new technology has major advantages, it has often also caused new stressors and problems for nurses. When Patient Accessible Electronic Health Records (PAEHR) was introduced in Sweden, research showed that nurses were worried about possible negative effects for patients as well as on their work. However, to this date there are very few follow up studies on the more long term effects of PAEHR, despite research pointing to the fact that reactions after long term use might differ from initial experiences. In this paper we present an interview study to fill this research gap. An analysis based on interviews with physicians and nurses in Oncology care reveals three areas where nurses' work is experienced to have been affected: 1) nurses receive more questions from patients after PAEHR has been introduced, 2) nurses have changed their documentation practices and 3) the log list functionality has made nurses feel questioned. Finally, these results are discussed in relation to nurses' work environment from a sociotechnical and gender perspective.

Keywords. eHealth, patient accessible electronic health records, work environment, nurse, interview

1. Introduction

The work environment in health care is indeed challenging and even though computer systems have managed to improve some areas and make them more efficient, they have also brought new problems and challenges into nurses' work. Nurses are currently faced with increasing workloads due to patients with co-morbidities, staff shortages and increased administrative work [1] [2] on top of new technology being implemented on a regular basis that has unwanted negative side effects for nurses [3].

When Patient Accessible Electronic Health Records (PAEHR) were launched in Sweden in 2012 nurses were skeptical to the system, which has been shown in a large survey study [4] and a small interview study in primary care [5]. Areas of worry related to the risk of PAEHR creating added work through changed work practises, changes in documentation practices, increased stress and worsened work environment. Other studies also pointed to nurses in psychiatry care worrying about PAEHR contributing to an in-

¹Corresponding Author: Jonas Moll, Örebro University, Fakultetsgatan 1, S-701 82 Örebro, Sweden; E-mail: jonas.moll@oru.se.

creased number of threats and violence due to patients knowing names of nurses, through the access log list, and being able to contact them [6] [7].

A sociotechnical system, such as nursing and PAEHR, cannot be properly understood without taking gender into account. Physicians and nurses do gender [8], i.e. perform what is expected from them as women and men in relation to other people, and in relation to technology. Studies on gender and technology reveal that communication patterns in nursing are influenced by gender and gender power, and that nursing is traditionally seen as a nurturing and emotional work [9]. However, too little is known about how the nursing profession is affected by technology.

Moreover, there are still very few studies looking into the experienced effect on work as PAEHR has reached a more mature use - most earlier studies in the area have been carried out within a year after launch. Initial experiences with and reactions towards new technical solutions, like the PAEHR in this case, are often different from experiences and reactions after more long-term use [10]. Given the current work environment problems in health care, this is a crucial area to look into from a societal perspective, and from a research perspective, more research is needed on the connection between digitalisation and the work environment. Additionally, most studies to date on the effect of PAEHR on the work environment of healthcare professionals have focused on effects for physicians [11] [12] [13] [14]. Hence, this paper looks into the experienced more long term effects of PAEHR on the work environment of nurses - an area which is under-investigated and in need of a qualitative research approach. More specifically the paper looks into the experienced effects on the work of nurses including general effects on workload and documentation and a specific technical part - the access log list.

2. Method

This paper reports on preliminary results from an interview study at Uppsala University Hospital. The study was ethically approved by the Regional Review Board in Uppsala (EPN 2017/045).

The results presented here are based on a content analysis of semi-structured interviews with 15 physicians and five nurses at the Oncology department. The interviewees were recruited through the head of department as well as the department's business developer. The interviews were held in rooms chosen by the interviewees, most often in empty examination rooms or private offices. Each interview took around 45 minutes and covered several topics, such as attitudes towards PAEHR, effects on work and effects on various aspects of communication with patients. The interviews were recorded and transcribed in verbatim prior to the analysis.

This paper focuses on results related to the effects on the work of nurses, including general effects on workload and documentation, and a specific technical part - the access log list - is treated in depth since it was shown to affect nurses in particular.

3. Results

The results describe in what ways PAEHR is experienced to have a clear impact on the Oncology nurses' work.

3.1. Nurses Receive More Questions as They Are the First Line of Support for Patients

According to the majority of the interviewed physicians, nurses in oncology care - and so-called *contact nurses* in particular - act as the first line of contact with patients. Consequently, patients ask nurses more often about health care conditions, test results and procedures. Accordingly, when patients call the hospital to ask for example about the information they have found in the PAEHR, they reach one of the nurses. According to several physicians, this has resulted in nurses receiving a lot of questions that they cannot answer questions that are then forwarded to a physician. An increase in questions from patients and questions that nurses cannot answer in particular - after the launch of the PAEHR is also confirmed in the interviews conducted with nurses in oncology care.

3.2. Nurses Have Changed Documentation Practices

According to some of the interviewed physicians, many nurses are more restrictive regarding what to write in the medical record now when the patients can access their health records online. This could, in some cases, lead to important information being left out of the medical record. A few of the interviewed physicians presented short incidents related to patients or relatives that became very upset when nurses had added a short note about the patient's mental health status - information that was important for the current treatment. In two cases, strong reactions on information found in the PAEHR had led to nurses deleting relevant information from the medical record.

3.3. The Log List Functionality Makes Nurses Being Questioned

In Region Uppsala, patients who log in to their PAEHR can use a function called *log list* to see which clinicians who have accessed their record and when access has been made. This particular function was brought up during some of the interviews as being problematic especially for nurses.

One of the issues brought up stems from the fact that patients often know the name of their primary physician, but not necessarily the name of the nurses connected to the care team around the patient. Nurses often access patients' medical records by request of a physician and they also often do routine checks of blood work or similar. In all these cases there is a chance that the patient will find unfamiliar names in the log list online. Some physicians reported that nurses were worried about this and they also reported on some cases when patients had asked a physician about unfamiliar names found in the log list. In all cases reported during the interviews, however, these kinds of questions from patients could be easily handled.

Another issue brought up in two of the interviews, related to documentation, is that some nurses often leave small snippets of information in the medical record to explain why access was made. These snippets do not add anything that could be seen as medically relevant, and hence these physicians were annoyed by them. The occurrence of these snippets was attributed to the existence of the online log list and interestingly enough the issue was brought up spontaneously by these two physicians before the log list had been brought up by the interviewer.

4. Discussion

The results presented in this paper highlight some effects of PAEHR on the work situation of nurses in oncology care. This is one of the few papers to date that reports on effects of PAEHR for nurses in any discipline and also one of the very first that covers effects several years after the launch of *Journalen* in Sweden. It is important to note that the number of interviewed nurses is relatively small. Even though clear problem areas have been identified, more research is needed that include a larger sample as well as interviewees from different medical disciplines.

It is clear from the results of the recent interview study that there are some clearly identifiable effects related to *patient contact*, *documentation practices* and *the access log list functionality*.

When it comes to effects of PAEHR on the contact with patients, both nurses and physicians experience that PAEHR has resulted in nurses receiving more questions from patients. The increased workload that is described could among other things be explained by the gendered norms related to the nursing profession. Nursing is traditionally coded as a female profession quite low in the hospital hierarchy, and the traditional terms that define nursing are emotional and nurturing work [9]. The contact between nurses and patients is also more often continuous and close, and the expectations for nurses are quite different from that on physicians when it comes to communication [15]. Physicians' meetings with patients, on the other hand, are more often fragmented, and short term. These differences among professions, the lack of research on effects of PAEHRs for nurses, as well as the pronounced effects for nurses shown in this study, highlights the importance of including nurses in these kinds of studies.

However, one should note that this increased workload for nurses when it comes to questions from patients might not be only negative in nature, as other studies have shown that person-centeredness in care has correlations with nurses' improved satisfaction with care and work [16]. More research is needed when it comes to the correlation between job satisfaction and the launch of PAEHR.

The perceived effects on documentation practices could also be a result of different gendered expected behaviours between the professions, looking at nursing as a traditionally female coded profession. Changed documentation practices might be understood in the light of women's more relational way of thinking. This indicates that women, more than men, notice and respond to other people's needs and expectations [17] [18]. In this case, nurses change and respond to the patient's need and expectations to understand PAEHR to a larger extent than physicians do as one way of doing gender [8]. This result could have implications for future nursing education especially when it comes to balancing the need to keep a complete and accurate record and the need to satisfy patients.

The log list function has been discussed in earlier research when it comes to effects of PAEHR on work, and especially perceived risks of threats and violence towards medical staff [6]. The results from the present interview study do not give any indication that nurses perceive any risk of threats or violence, but the existence of the online log list still has an impact on actions taken by nurses. The very nature of the nurse profession - in this case being a part of a team who may work with many doctors, and often not

being known by his/her name by the patient - is at the core of the problem. There is a clearly described insecurity here in relation to documentation, and an obvious need to explain one's presence in the electronic health system. More research is needed into the gendered explanations of this in the sociotechnical system.

Online Medication Information for Citizens: A Comparison of Demands on eHealth Literacy

Helen MONKMAN^{a,1}, Thomas SCHMIDT^b, and Christian NØHR^b

^a*School of Health Information Science, University of Victoria*

^b*The Maersk Mc-Kinney Moller Institute, University of Southern Denmark*

Abstract. Many people take prescription medications and need information about the risks and benefits associated with taking them. Citizens are increasingly turning to the internet for health information and medication information is no exception. There are a variety of websites that offer Online Medication Information for Citizens (OMIC). This study compared six such websites using the Health Literacy Online (HLO) Checklist as a framework. Additionally, we conducted a detailed analysis of the individual content in each OMIC for three different medications. We identified several strengths and weaknesses of the different websites in terms of how they were designed and written and their appropriateness for users with limited eHealth literacy.

Keywords. Consumer health informatics, medication information, health literacy, eHealth literacy

1. Introduction

Worldwide spending on pharmaceuticals (i.e., prescription medications) reached 1.2 trillion in 2018 and is projected to continue increase in the coming years [1]. Many North Americans use short-term and/or long-term prescription medications and use invariably increases with age [2, 3]. Given the prevalence of prescription medication use and the risks and benefits of taking medications, people need information about them. The most commonly used resources for medications are patient information leaflets, doctors, and pharmacists [4]. However, the internet gaining popularity as a resource for medication information, especially younger people [4].

This study assessed how well Online Medication Information for Citizens (OMIC) was designed for users with limited health or eHealth literacy in terms of both its content and design. Specifically, three prescription medications from six online resources were examined to determine their relative strengths and weaknesses using the Health Literacy Online (HLO) Checklist [5] as a framework with a complementary in-depth examination of each OMIC's individual content [6]. HLO is provides evidence-based guidance to assist in the development of "user-friendly health websites and digital health tools" [6].

¹ Helen Monkman, E-mail: monkman@uvic.ca

2. Methods

We assessed OMIC from six different Websites for three different medications: Asmanex (mometasone inhalation), Crestor (rosuvastatin) and Humalog (insulin lispro) (see Table 1).

Table 1. Websites Examined Offering Online Medication Information for Citizens.

Website	Type of Resource	Medication Information Data Source
Rexall.ca	Canadian pharmacy	MediResource Inc.
Walgreens.com	American pharmacy	Clinical Drug Information LLC
Min.Medicin.dk	National Danish medication information resource	Danish Medicines Information A / S
WebMD.com	Health information resource	First Databank, Inc.
MayoClinic.org	Not-for-profit health information resource	IBM Watson Micromedex
Drugs.com	Independent medication information resource	IBM Watson Micromedex, Cerner Multum™, Wolters Kluwer™ and others

We compared each website against the four applicable categories of the Health Literacy Online Strategies (HLO) Checklist: *Write Actionable Content*, *Display Content Clearly on the Page*, *Organize Content and Simplify Navigation*, and *Engage Users* [5]. The category *Test Your Site with Users with Limited Literacy Skills* was excluded because this was an inspection study.

We used word count and Simple Measure of Goobledygook (SMOG) scores [7] as indices of HLO Checklist's guidance to write in plain language in the Write Actionable Content Category. SMOG [7] scores are derived using a calculation of the number polysyllabic words in a sample sentences to estimate of how many years of education are required to understand the text. To this end, Danish OMIC from min.medicin.dk, was translated to English using Google Chrome and each OMIC was converted to a simple text document (either through print functionality or copying and pasting). We then determined each OMIC's SMOG score using an online readability calculator [8]. Notably, we excluded the information on the "professional" tab of Drugs.com, as it was not for the target audience of citizens. We calculated the average number of words and average SMOG scores for each website.

Additionally, to assess the content in greater detail, we used a previously developed set of criteria for content utility which outlines 11 helpful topics for medication information: benefits, contraindications, directions, precautions, adverse effects, storage, missed dose, allergic reaction, drug interaction, overdose, and general information [6]. We averaged the number of content criteria satisfied amongst the three OMIC per website. Further, we examined each OMIC's reported side effects to determine whether there was conflicting medication information [9].

3. Results

3.1. Write Actionable Content

Min.medicin.dk (1,296 words) and Walgreens (1,501 words) used the fewest words on average for their OMIC. Drugs.com was the lengthiest, with an average of 4,507 words. Walgreens had the most readable content, with the lowest average SMOG score of 8.47. The remaining five websites' average SMOG scores ranged from 11.69 for

WebMD to 14.51 for Drugs.com. As alluded to in the methods, Drugs.com also contained information for professionals in the form of a tab and as additional content in its side effects tabs. This has the potential to create confusion for users and unnecessarily overwhelm them. In contrast, Min.medicin.dk offers an alternative site specifically for professionals (pro.medicin.dk). Drugs.com and Rexall had many bullets and lists, whereas others had fewer (e.g., WebMD, MayoClinic) or almost none (i.e., Walgreens).

3.1.1. Content Utility and Comparison of Potential Side Effects

Min.medicin.dk satisfied the fewest content criteria (73%), followed by Rexall (82%), Walgreens (88%), Drugs.com (88%), and the MayoClinic (91%). WebMD (97%) satisfied the most content criteria.

There was considerable variation between which possible side effects were reported, how many in total, as well as how they categorized the potential side effects. Specifically, Min.medicin.dk reported the fewest possible side effects amongst all of the websites, whereas the MayoClinic and Drugs.com reported the most. There were also discrepancies with the language used to describe or categorize possible side effects: some websites focused on frequency of occurrence (e.g., more common, less common, rare, may occur, unlikely) and others focused on severity (e.g., very bad, serious) or both frequency and severity. Arguably, Min.medicin.dk utilized the clearest approach to describe the frequency of side effects by using numbers. For example, they reported maximums of “10 out of 100 people get the side effect” (common), or “1 out of 1 people” (uncommon) and “1 out of 1,000 people (rare) as well as unknown frequencies of possible side effects. In terms of text presentation, Walgreens was the least structured and most difficult to read and extract information due to its format. Specifically, the information was all presented in big blocks of text with capitalized letters to attract attention or serve as headings. Additionally, Drugs.com listed additional possible side effects and frequencies for health care professionals that were categories by medical specialty (e.g., gastrointestinal, nervous system, respiratory) and labelled more common (10% or more), common (1% to 10%) or uncommon (0.1% to 1%). Some sites listed side effects that do not require medical attention, but which may still cause consumer concern.

There was no consensus on which possible side effects were reported or how they were reported. For an illustrated example, to compare whether or not a possible side effect was reported by each site and how it was labeled is provided in Table 2.

Table 2. A Comparison Sample of Possible Side Effects for Reported by Each Website for Asmanex

Website	Fever	Cough	Nausea	Headache
Rexall.ca	*	✓	✓	✓
Walgreens.com	✓	✓		✓
Min.Medicin.dk				✓
WebMD.com	*	✓		
MayoClinic.org	✓	✓	✓	✓
Drugs.com	✓	✓		✓

Legend: ✓ = Possible side effect reported. * = Reported as a sign of infection, not as a possible side effect.

3.2. Display Content Clearly on the Page

Some sites displayed their content more clearly than others. Specifically, Walgreens and Min.medicin.dk were both spacious and visually appealing. They achieved this by

using collapsible categories. The selected categories varied greatly amongst sites. Walgreens listed just five selection options (Instructions, Side effects, Patient reviews, Pricing, and PDF download). At the other end of the spectrum, min.medicin.dk lists 16 selection options such as active compounds, packaging, precautions related to breast feeding, pregnancy, and donating blood. Drugs.com contained several advertisements which not only gave it a busier appearance but could potentially distract users from the main content. Similarly, WebMD had many links, which could encourage users to navigate away from the page before reading its entirety. Further, on almost every tab on WebMD, users had to click the “read more” button to reveal the remaining content. WebMD also had an excessive amount of links and not enough bullets or short lists. With the exception of Rexall, nearly all of the websites provided some helpful images of pictures of the medications. However, Min.medicin.dk leveraged multimedia further for medication instructions. MayoClinic and Min.medicin.dk provided buttons and printer friendly versions of the OMIC. Walgreens allows users to download PDFs of the OMIC and Rexall can be printed using the browser. However, WebMD and Drugs.com did not offer printer friendly options.

3.3. Organize Content and Simplify Navigation

Search functionality varied amongst the six resources. Min.medicin.dk, Drugs.com, Walgreens and WebMD demonstrated strong search functionality by supporting users with auto-complete and offering suggestions for misspellings. However, Rexall and WebMD returned no results for misspelt medications. Moreover, Drugs.com and WebMD search results were displayed below advertisements and therefore disobeyed the HLO Checklist [5] guidance to display search results clearly. Despite having autocomplete functionality, the medications were not suggested by the MayoClinic. Further, the MayoClinic’s search results only named the generic name of the medication and not the brand name, which could lead users to falsely conclude their search was unsuccessful. We tested the responsiveness of all six websites and found to be present using the developer functions of Google Chrome.

3.4. Engage Users

Only Rexall and Drugs.com demonstrated strong sharing capabilities by providing options on each OMIC page to share the information on social media (e.g., Facebook, Twitter). Min.medicin.dk did not support sharing to social media, but it did provide an option to email the link, as did Drugs.com. Walgreens (sourced from PatientsLikeMe) and Drugs.com also included patient reviews of the medications on their sites.

4. Discussion and Conclusion

There were several strengths and weaknesses of the six websites in this investigation. Overall, the strongest site in terms of placing the fewest demands on users (i.e., abided by the guidance of the HLO Checklist) was Walgreens and its content was the most readable and easy to navigate. However, despite performing well on the metrics, the information itself poorly formatted. Specifically, Walgreens content was frequently dense walls of text. Thus, it is important to note that despite satisfying many criteria, there is still substantial room for improvement of its content (e.g., use bullets and short

lists). Moreover, are some HLO Checklist criteria more important (i.e., impact users more) than others? Should they be weighted?

Alarming, there were discrepancies between how the websites reported possible side effects. Specifically, some reported possible side effects, while other websites did not report the same ones (see Table 2). Conflicting medication information has been shown to negatively impact adherence [9] and therefore there are likely consequences to these OMIC side effect discrepancies. Further, how websites categorized varied by emphasizing frequency of occurrence or severity of experiencing the side effects, concepts often confused by citizens [10]. Moreover, how frequency of occurrence using either a vague label (e.g., common) or specific value (e.g., 1 in 100 people) could have an effect on citizens' interpretation and might also impact adherence.

There were some limitations to this study. We only examined three medications from the six websites. Further, we excluded pharmaceutical manufacturer information. The Danish OMIC was translated using Google Chrome which is an imperfect proxy. Additionally, websites that did not provide a print option (i.e., Drugs.com, WebMD) were copied and pasted and excluded the redundant content that around the tab areas. Finally, we neither tested the accessibility nor the mobile versions of the websites.

There are a variety of OMIC options available to citizens and each website in this study had its strengths and weaknesses. Based on the current evaluation, we recommend that these websites make an effort to improve the consistency of information they are providing to citizens, to limit conflicting medication information. Further, findings from this study could be incorporated to improve the OMIC and its adherence to the HLO guidelines for simplicity of navigation and content itself and also its structure are warranted. Future research opportunities including comparing the influence of health care system structure, culture, and prescription practices internationally (e.g., North America vs. Europe), as how citizens select amongst OMIC alternatives, and finally how these resources might be designed to address the needs of people with varying eHealth literacy skills.

^c*Informatics, School of Business, Örebro University, Örebro, Sweden*

Abstract. Patient portals are used as a means to facilitate communication, performing administrative tasks, or accessing one's health record. A qualitative study was therefore performed to understand how people with hearing loss experience using the Swedish national patient portal 1177.se and the patient accessible electronic health record *Journalen*. Data was collected through focus groups and individual interviews. Ten persons with varying degree of hearing loss, age and years of using a hearing aid participated. The data was analyzed through thematic content analysis and three themes emerged; access to written information, patient-created information and personalized communication. Although the study is limited in size, we believe that important lessons can be learned regarding the needs for personalized communication, including access to written information.

Keywords. Patient portals, Electronic health records, Hearing loss

1. Introduction

Patient portals are used to facilitate communication between patients and healthcare professionals, as well as for performing administrative tasks, such as appointment bookings and prescription renewals. Patients are also increasingly provided with access to their electronic health records (EHRs), sometimes referred to as patient accessible EHRs (PAEHRs) [1][2] or OpenNotes [3], through portals. Most of these systems are designed to meet the needs of the general population, and few studies are available on how patients with special needs experience the use of such systems. In Sweden, a national patient portal is used that connects to all EHR systems used in the different regions [2], through a national health information exchange platform [4]. By logging in using a national e-ID one can access a number of administrative services as well as the PAEHR *Journalen*. In July 2019, 61% (6.3 million/10.3 million) of the Swedish population had logged in to the portal, and 29% (3 million/10.3 million) have used the PAEHR *Journalen* at least once [5]. Several studies have been performed exploring patients' and healthcare professionals' views on *Journalen* [6][7], but to our knowledge, no studies have focused on how persons with hearing loss use and experience the patient portal 1177.se and *Journalen*. Since this group of users have additional needs regarding

¹ Corresponding Author, Maria Hägglund, Department of Women's and Children's Health, Uppsala University, Dag Hammarskjölds väg 14B, 752 37 Uppsala, Sweden. Email: maria.haggglund@kbbh.uu.se.

communication and access to information, we aim to explore their experiences of using the Swedish national patient portal 1177.se and the PAEHR *Journalen*, as well as their suggestions for future improvements.

2. Methods

Hearing aid users who had used 1177.se and *Journalen* were recruited through online advertisements spread through social media and patient organizations. The participants (n=10) were recruited from different parts of Sweden, and given the option to join a focus group interview or to participate in an individual interview, in person or over the phone. Two focus groups were conducted; in Uppsala and Stockholm. Each focus group lasted 90 minutes. Three individual interviews were conducted by telephone and lasted approximately 40 minutes. A validating workshop was conducted using raw data from focus groups and interview, confirming the results that emerged and is therefore not reported separately. The participants represented a variation of age, gender, severity of hearing loss and years of using hearing aids (Table 1).

Table 1. Demographics of the participants (n=10). U = Uppsala FG, S = Stockholm FG, I = Interview, V = Validating workshop

Participant ID	Gender	Age	Years using hearing aids
U1	Male	47	10
U2	Male	76	5
S1	Male	51	44
S2	Female	40	12
S3	Female	47	42
I1	Male	69	6
I2	Male	82	16
I3	Female	75	20
V1	Female	75	15
V2	Female	74	1

Data were analyzed using a thematic content analysis approach, providing a rich and thorough, interpretation of the data [9]. The analysis was done manually and in iterative dialogue between the authors. The Swedish Ethical Review Authority granted ethical approval for the project PACESS (Dnr: 2017/1028-31).

3. Results

Both current experiences of using 1177.se/*Journalen* and participants’ suggestions for future improvements were discussed. Three themes were identified; access to written information, patient created information and personalized communication.

3.1. Access to written information

Having access to written information in general and the notes from the electronic health record, in particular, was described as very important by the participants. Depending on the gravity of the participants hearing loss, it required a lot of energy and focus to listen to what clinicians said during an appointment. Some of the participants described that they focused so hard on hearing what the person said that they couldn’t process and

remember much of the information. Being able to go back and review notes then became even more important.

Access to the record as a safety tool. A few of the participants described that having access to record notes was also a patient safety issue, as they could see when the information was missing or wrong.

"When I saw that things were missing in my health record I contacted the clinic and asked why." (U1)

Improved understanding with access to record notes. Reading the health record online gives the patient a summary of what was said during the meeting. Having the option to read their health record online was described as a means to improve communication with healthcare.

"I get a summary of what we have been talking about during the care visit. Things that I have misunderstood during the actual meeting, I can go in and read about in my health record to understand what the healthcare professional meant." (U1)

Specific information for hearing aid users. Several participants reasoned that they would like the hearing clinic to post more specific information for hearing aid users on 1177.se, e.g. related to specific services that hearing aid users may benefit from.

"New hearing aid users are extremely dependent on their audiologist and the information provided by the audiologist. More information about this should be available at 1177.se." (S1, S2, S3)

A few of the participants would also like self-management films on 1177.se on e.g. how to care for the hearing aid.

Diagnostic examination results. All the participants had ideas for what kind of diagnostic examination results they would like to see on 1177.se; audiograms, X-rays and ECG (this type of information is currently not available). Some of the participants received paper copies of their audiogram when they visited the audiologist others received the audiogram as a pdf file to their email. Several participants would rather have it accessible through 1177.se

"I received my audiogram on paper, and after the visit, I took a picture of it with my phone, so I could have it accessible, but I would rather have it on 1177.se." (S2)

3.2. Patient created information

The participants did not only want access to more and better information, they also wanted to contribute with their own information to healthcare through 1177.se. Three different types of patient created information was suggested.

Add attachments to messages. In one of the focus groups, the participants wanted to send attachments with messages through 1177.se, for example, sending medical certificates in attachments.

"I had contact with my counselor through e-mail and she asked if we could take the errand through 1177.se instead but that was a problem because I was not able to send attachments with my medical certificate through 1177.se" (U1)

Add information about hearing and medical aids. A list or a profile where patients could add information about what hearing and medical aids they use was also suggested. Having a list or a profile makes it easier for other healthcare providers or other audiologists to know what the patient already use.

"I would be good if there were some kind of list on 1177.se of what hearing aids and medicals I use so that I could go in and add things and perhaps write instructions how my different aids work and how they are set." (U1, U2)

Commenting/adding to their own health record. At the moment, the only functionality for most users of 1177.se/Journalen is the ability to read their health records. In the Uppsala Region, it is, however, possible for patients to make comments in the record that healthcare professionals can read. A few of the participants thought that this function would help them reflect and remember things about their health and that it could also save time during the actual health meeting.

"When I read my health record entries, I get ideas and remember things about my health from several years ago and this I would want to add to my health record. It would also save time for both myself and the healthcare provider. /.../ it would also help me bring this up in the next meeting" (U1)

3.3. Personalized Communication

Communication with healthcare and the importance of the national patient portal for users with hearing loss in this communication was an important topic.

Impact of hearing loss on communication with healthcare. Several participants reasoned about how their lack of hearing affected their communication with healthcare. Many did not use the telephone when contacting healthcare since their hearing loss increases the risk for misunderstandings, and were happy that 1177.se provides means for written communication instead.

"I never use the telephone when contacting healthcare because I have a really hard time hearing what they say, I use 1177.se so I don't miss important things." (S2)

Yet, several of the participants expressed frustration that despite their hearing loss, healthcare would insist on using the telephone when initiating contact.

"For me, it doesn't work at all. My health record from the hearing aid clinic states that I am deaf and cannot receive phone calls. SMS or messages via my 1177.se works but despite this, I get calls from healthcare professionals." (U1)

Participants with less severe hearing loss used the telephone to communicate with healthcare, and it was clear that different individuals had very different needs.

Lack of dialogue through 1177.se. Users of the patient portal 1177.se can send messages to their healthcare providers. Several of the participants reasoned that sending and receiving messages worked well through 1177.se but after receiving an answer the dialogue ended, and they could not send anything back.

"I think it's good that you get answers, but there is no dialogue or feedback. It's difficult to have a discussion if there's something you want to explain or bounce ideas. It works when you want to book lab tests or renew prescriptions." (S2)

Communication and equality. Participants described different ways of communicating with their audiologist/hearing clinic. Some had direct email contact with their audiologist and appreciated this but were aware that this was a special case.

"The audiologist does not give out their e-mail address to whoever. /.../ But I have contact with my audiologist via e-mail." (S2)

Alternative online communication methods. Participants wanted to be able to send messages directly to the audiologist through 1177.se, but they also proposed a chat function with receptionist/nurse or using a videophone.

"Videophone, sign language chat should be offered." (S1, S2, S3)

Handling appointments. Currently, patients receive appointments from many healthcare professionals in a variety of formats (oral, paper and in some cases electronic). Many of the participants would prefer booking appointments online.

"Appointment booking to my audiologist would be better if it was digital." (I3)

Others reasoned that there should be an easier booking system in 1177.se and that healthcare professionals should be able to send appointment bookings digitally.

“Easier appointment booking system on 1177.se like a guide that would help you if you not sure how to book an appointment.” (S1, S2, S3)

Ensure awareness of a person's hearing loss among healthcare professionals. Many of the participants were concerned that healthcare professionals did not always know that they had a hearing loss. Information should be clearly visible in the patient's health record and healthcare professionals' portal interface, perhaps in the format of a patient profile, to both reduce the risk for communication problems and save time during visits, for now, hearing-related health issues.

“Other healthcare professionals should know I have hearing loss.” (S1, S2, S3)

4. Discussion and conclusion

Although a fairly small group of people participated, the in-depth interviews provided a rich material that clearly indicates some of the challenges experienced by people with hearing loss in their communication with healthcare, and highlights benefits that digital tools can and do provide for these users. Further flexibility and adaption to individuals' needs and preferences are still needed to fully support people with hearing loss. Improved tools for written communication and access to clinical documentation can provide such support, and would likely be beneficial to other users.

^c*Department of Medical Informatics, National Cancer Center Hospital, JAPAN*

Abstract. Health information systems (HIS) and clinical workflows generate medication errors that affect the quality of patient care. The rigorous evaluation of the medication process's error risk, control, and impact on clinical practice enable the understanding of latent and active factors that contribute to HIS-induced errors. This paper reports the preliminary findings of an evaluation case study of a 1000-bed Japanese secondary care teaching hospital using observation, interview, and document analysis methods. Findings were analysed from a process perspective by adopting a recently introduced framework known as Human, Organisation, Process, and Technology-fit. Process factors influencing risk in medication errors include template- and calendar-based systems, intuitive design, barcode check, ease of use, alert, policy, systematic task organisation, and safety culture. Approaches for managing medication errors also exert an important role on error reduction and clinical workflow.

Keywords. Medication error, health information systems, evaluation, workflow, lean, case study

1. Introduction

Despite the potential of health information systems (HIS) in reducing medication errors, HIS have been associated with new types of medication errors [1]. This paradox is primarily attributed to HIS misfit with the work patterns and settings of health care, resulting in the inefficient use and unintended impact of HIS in error reduction. The prevalence of HIS adoption and safe application remains at its infancy due to technical and organisational challenges [2, 3]. Further research is required on work organisation problems, cooperative work problem [2] and identifying safe practices for managing information technology (IT) transition. A close look at clinical process management can demonstrate the overall process, its specific steps in identifying the control mechanism and error risk and its impact pertinent to HIS-induced errors. This paper reports the preliminary findings of a case study on the management of HIS-induced medication errors from a process perspective in clinical practice.

¹ Corresponding Author. Maryati.Yusof@ukm.edu.my

2. Theoretical background

The proposed Human, Organisation, Process and Technology-fit (HOPT-fit) evaluation framework was developed after critically appraising the literature [4]. Previous error models were also used to categorise evaluation factors, dimensions and measures. As an organisational element, process is featured as one of the factors and is represented as the dashed line that links process and organisation in Figure 1. Process plays a central role in error failure and management because errors are commonly triggered during the execution of a process. The developed framework proposed three dimensions of process: the clinical stages, business process management (BPM) life cycle and lean methods. This study focused on medication errors; thus, it examined the stages of medication and its compliance with the five rights: right drug, dose, route, time and patient (5R). Process management can be assessed in accordance with various stages of BPM. Meanwhile, process quality and safety can be examined using various lean tools and methods.

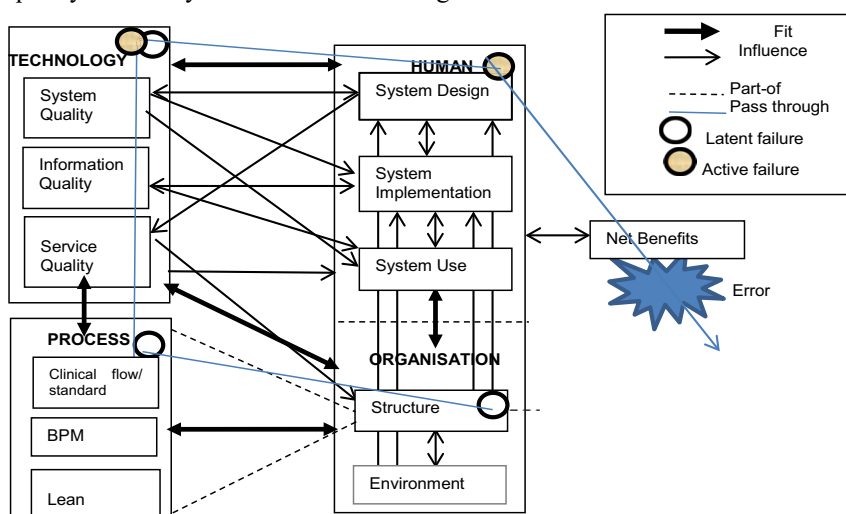

Figure 1. HOPT-fit framework (adapted from [4]).

3. Method

A summative case study evaluation was conducted in actual clinical settings to explore the context and nature of the event to be investigated. Data were gathered using interview, observation and document/artefact analysis. We studied a number of HIS in a 1000-bed Japanese secondary care teaching hospital (SCTH). Face-to-face and written interviews were audio- and manually recorded and then transcribed in English and Japanese by translators. Using a purposeful snowball sampling method, 13 informants among clinicians and management committee were interviewed. Four techniques were used to analyse the results: coding, analytic memos, contextual analysis and narrative analysis. To understand medication error management holistically, data were analysed using process approaches [5, 6]: 1) Major medication processes in an end-to-end clinical process were identified and structured into five sub processes, from prescribing to monitoring. 2) A process step table was constructed; it includes process information flows and owners. 3) Process error risks were summarised, and their sources (input,

process or output flaws) and subsequent impact were identified. 4) Activities that serve as preventive, detective or corrective controls were determined.

4. Results

Medication use (MU) for the SCTH's inpatients was documented using a process step table that featured the medication process, control, flaw, and impact. MU steps were identified based on the MU process for hospital and long-term cases [7]. The SCTH additional processes is nearly double the number of those of MU. The selected steps, error control, flaw and impact are provided in Table 1. The medication process for the STCH inpatients involved several HIS, and a safety measure is implemented on every possible point of care. The doctor *prescribes* medicine in the consultation room using a computerised provider order entry (CPOE). The medication order is sent to the pharmacy department for drug preparation. The doctor gives order instructions to the nurse through a calendar, template-based instruction system (InstS). The nurse receives the instruction. The doctor checks whether the nurse has seen the instruction (indicated by a changed coloured display). The nurse sees the new doctor's instructions that are highlighted in different colour. When the nurse checks it, he/she can post questions to the doctor or clicks the 'received button' to confirm the receipt of the doctor's instruction. The pharmacist checks the order data on Pharmacy IS (PhIS), downloads the data to PhIS, prepares the drug envelope and sends the envelope and drug to the nurse station for dispensing the medication to the address entered in a mechanical cart. The nurse delivers the envelope to the ward for administration. STCH policy requires the preparation of a one-dose package to avoid confusion.

Changes in the doctor's order are designed with error control but are still prone to errors. Error risk may occur when the doctor changes the order but the nurses are unaware of it because they do not always check the system. Therefore, the system should ensure that nurses are informed about changes. If the doctor changes instructions before a drug is mixed, then the nurse will print the mixing sheet with a new bar code. Otherwise, if the nurses check the old mixing sheet bar code against the new bar code update in the system, then an error alert is prompted due to bar code mismatch. Similarly, if a change is made after an order is sent to the pharmacy, then the pharmacy does not know about the change. The drug may already be delivered but administration should be stopped. The instruction system is updated with the change and the medicine should be returned to the pharmacy. The new mixing sheet is printed out. The information in the pharmacy system is only updated if drug quantity increases.

5. Discussion

The current study adopted the core processes and adapted them to MU processes that are unique to the SCTH setting. The process model is beneficial for modelling the overall process, ensuring the inclusion of basic processes and arranging them in a structured and systematic manner. Breaking down the process to the simplest task unit enabled the discovery of process variance, barrier, error risk, and fit with HIS that are otherwise overlooked in the SOP. The process of determining step breakdown and classifying it as either a step or control, a single or a sub step is challenging. Optional activities are

explicitly modelled due to their intuitive manner and positive influence on ‘the structural complexity and the understanding of the process flow’ [8].

Table 1. Selected medication process, control, risks and impact

Process steps [resource(s)]	Control and impact	Error risk and impact
Prescribing		
P1.1 Make clinical decisions	Calendar-based interface, graphical symbol and colour - AL	Overlapping medication - VACT
P1.2 Select drug		
P1.3 Determine drug regimen	Automated dosing and calculation – ACT; Alert - A	Alert override - ART Excessive alert - R
<i>P1.6 Stamp prescription</i>	Identity authentication - V	
<i>P1.7 Submit order</i>	Daily-based drug - AT	
<i>P1.8 [O] Change order</i>	Must cancel previous order - A	Incomplete changes - VAT
<i>P1.9[O] Submit order change</i>		
Instructing		
I2.1 Send instruction	Template, calendar-based interface-L; Timing-based drug - LT	
<i>I2.7 Check if order is received</i>	Automated colour-coded change - LAT	
<i>I2.8 [O] Send change order instruction</i>	Prevent instruction overlap – VAT; Change message – ALT; View nurse check - AT Highlights in MD interface - LT	Nurse does not check changes – VACT; Nurse forgets to exclude stopped medication or include added medication - VACT
<i>I2.8 [O] Check seen changes</i>	Disappeared highlights	
Transcribing		
T3.1 Check order data	Correctness check: IF before Ph. check → THEN OK; IF after Ph. check → THEN error - VAT Automated colour-code change - L	Change is made after order is sent to PhIS and drug is prepared - VACT
<i>T3.2 Download data to PhIS</i>		
Dispensing		
D4.1 Enter and screen data	SOP - VACT	
<i>D4.2 Prepare drug envelope</i>	Completeness of patient and drug information - VACT	
D4.3 Prepare, mix and compound drug	5R, patient-drug bar code match: IF before drug mix → THEN OK IF after drug mix → THEN error message – VACT Prepare one-dose package - AT Two independent nurse checks - VA	Error can occur if the system is not checked before injection drug mixing - AT
D4.4 Dispense to nurse station	Dispensing and cart machine - AT	
<i>D4.5 Dispense to ward</i>		
Administering		
A5.3 Nurse verifies order	5R, patient-drug barcode match: IF match, THEN OK; IF mismatch, THEN prompts error alert- VACT	Nurse does not check the system or use the barcode before administering - VACT
A5.4 Administer drug	Colour code for taken, delivered and undelivered drugs -VACT	Nurse forgets to take out stopped drug or add new drug - VACT

Notes: Italicised step = unique to SCTH Ph. = pharmacy; 5R = 5 rights; Data quality measures: validity (V), accuracy (A), timeliness (T), completeness (C), relevancy (R), legibility (L)

STCH has established various controls to ensure patient safety including intuitive design using template, calendar, and automated functions. However, several controls are

also error-prone. Subsequent flaws that penetrate through the aligned control mechanisms from all four HOPT factors will result in an error incident. By contrast, several error risks have no control mechanism. Continuous monitoring and evaluation through lessons learned can improve HIS development and use, fitting it with the clinical process to prevent recurring errors. In addition, safety culture and Japanese Kaizen approach, which focuses on continuous incremental improvement, has been proven to yield significant results over time in STCH.

Although the study was conducted at specific, clinical settings of one hospital over a short duration, the data were collected rigorously and systematically, yielding to in-depth findings that are also applicable to other clinical contexts. Additional feedback was obtained from the participants to clarify and gain more information.

6. Conclusions

Every process step is prone to errors, but several steps have a control mechanism to prevent or minimize error. Human intervention is still required in tandem with system intervention to avoid errors. The case study findings also demonstrate the feasibility of the process approach to address process as one of the essential components of IS, and the fit between the HOPT factors. This evaluation approach is potentially useful to researchers and practitioners for conducting rigorous evaluation studies. Lessons can be learned from this study's findings and recommendations for improving HIS development and process management can be identified to guide the future development of HIS, increasing its effectiveness and improving patient safety.

Abstract. Psycho-social factors are often addressed in behavioral health studies. While the purpose of many mHealth interventions is to facilitate behavior change, the focus is more prominently on the functionality and usability of the technology and less on the psycho-social factors that contribute to behavior change. Here we aim to identify the extent to which mHealth interventions for patient self-management address psychological factors. By understanding users' motivations, facilitators, and mindsets, we can better tailor mHealth interventions to promote behavior change.

Keywords. Self-management, apps, behavior change, psycho-social factors

1. Introduction

Mobile health (mHealth) technologies (e.g., smartphone apps or wearables), affect patients' self-management (SM), clinical care, and health research. Especially for those with chronic health conditions like diabetes, mHealth enables patients to gather relevant data such as information about blood glucose, diet, and physical activity to better understand their health and make decisions about diabetes SM. With this knowledge at their fingertips, patients are now encouraged to participate in their care by sharing mHealth data with their healthcare providers (HCPs). As patients do this, HCPs will need to adjust their approach to patient care and guidance, and health researchers need to understand how mHealth technologies impact the ways patients and providers work together.

The purpose of most health and mHealth interventions for lifestyle-related health issues, e.g. diabetes, is to facilitate health management and, if necessary, behavior change. Research on mHealth interventions has focused on user experiences, with some pre-post measures of health behavior change, e.g. frequency of blood glucose measurements. However, less attention is placed on users' environments, motivations, or interactions with others [1]. Both internal (e.g., self-efficacy, sense of control, mindsets about health) and external factors (e.g., social

¹ Corresponding Author: Meghan Bradway, E-mail: Meghan.Bradway@ehealthresearch.no.

connection, communication, and the patient-provider relationship) influence the process of health behavior change. If we do not address these factors within mHealth intervention studies, we will not be able to understand the comprehensive impact of such technologies.

We propose that it is critical to design research questions that capture psycho-social factors in behavior change. Therefore, we have assessed the prevalence of questions related to these concepts in mHealth intervention studies, thereby revealing current gaps and future directions.

2. Methods

We aimed to identify articles that were published after the release of the 2015 Guidance for Industry and Food and Drug Administration Staff regarding how to address mHealth technologies [2]. These articles would thereby reflect the most updated efforts to assess new mHealth technologies, including those that address these new guidelines. We reviewed studies published in English between Jan. 1, 2015 and Jan. 18, 2019, describing mHealth interventions for patient self-management of WHO’s listed major chronic non- communicable diseases (NCD) [3], as well as chronic mental illnesses. We searched Medline, PubMed, Google Scholar, and ProQuest Research Library for combinations of “mobile application” or wearable, and self-management or self-efficacy, and patient. We focused on qualitative questions asked in the following methods: study-specific questionnaires, interviews, and focus groups. Methods that described the purpose of the inquiry, e.g. satisfaction, without listing the questions themselves, were also included. Questions asked to both patients and HCPs were then grouped under emergent themes and then overarching categories: user experiences and four major psycho-social theories of behavior change: behavior change intentions, facilitators/barriers, measures of behavior change.

3. Results

The search resulted in 31 articles. Twenty-four articles included qualitative questions (Figure 1).

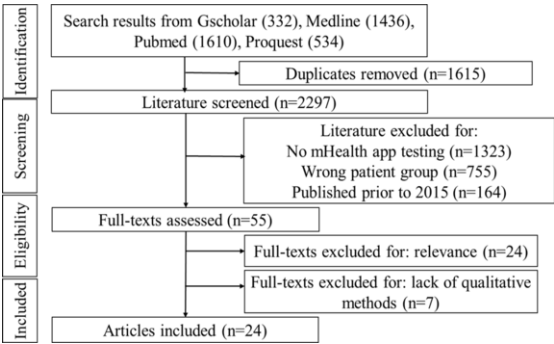

Figure 1 PRISMA diagram describing the selection of articles for data synthesis.

Emergent categories (n=18) were identified, and then grouped under broader categories (n=4).

We identified 204 questions and six articles that did not list their questions but, instead, described the topic of their inquiries. *User experience* was the most represented category (n=103 questions in n=13 articles, and n=5 articles addressing this category). Other inquiries focused on motivation, goals, and control [22], daily or SM habits [23, 24], confidence in future use [25] and focus on intention of use [26]. It is important to note that articles cited under a category may contain few questions that address that category, e.g. Fortuna et al. only included one question that addressed the category *Facilitators and barriers* [4]. Two of the seven articles that used interviews included questions that expanded upon previous feedback, e.g. “Anything else?”, “What makes you say that?”. While it was most common that patients were the target of inquiries (n=192 questions addressed to patients), three studies queried HCPs on satisfaction, experiences, and expectations (n=13 questions, n=1 interview).

Categories [Refs]	Sub-categories (n=questions)	Example questions or statements
User Experience [4-21]	<ul style="list-style-type: none"> • Experience (n=43) • Usability (n=24) • App description (n=19) • Usefulness/efficacy (n=5) • Satisfaction (n=8) • Suggested improvements (n=4) • Questions described, not listed (n=5 articles) 	<ul style="list-style-type: none"> • What were the main issues/difficulties you were facing when using the system? • The app had a remind/alert functionality • Overall, I am satisfied with how easy it is to use the App • (Nurse) Viewing daily measurements allowed nurses to recommend treatments
Measures of behavior (SM), health, or lifestyle change [5, 6, 10, 12, 22-24]	<ul style="list-style-type: none"> • SM behaviors or tasks (n=14) • General health (n=7) • General life and habits (n=6) • Mood (n=2) 	<ul style="list-style-type: none"> • The Fitbit helps me be more active • How did you feel this morning when you woke up? • How healthy do you think your diet is? • I often forget pills or take them late
Behavior change intentions [4, 5, 8, 10, 11, 15, 19, 22, 25, 26]	<ul style="list-style-type: none"> • Intentions (n=27) • Expectations (n=20) • Questions described, not listed (n=1 article) 	<ul style="list-style-type: none"> • (Provider) How confident are you that you will use the data from HeartMapp for decision making on patient care? • How likely do you think this app will help you lead a healthier lifestyle for better control of your diabetes • How comfortable would you feel sharing the information on this app with a family member or close friend?
Facilitators and barriers to behavior change [4, 6, 15, 22, 25]	<ul style="list-style-type: none"> • Self-efficacy/ autonomy (n=11) • Needs were/were not met (n=9) • App would facilitate control over SM (n=3) • Motivation (n=2) 	<ul style="list-style-type: none"> • I know what helps me stay motivated to care for my diabetes • I am able to turn my diabetes goals into a workable plan • I can ask for support for having and caring for my diabetes when I need it

4. Discussion

The number of questions related to *Behavior change intentions* and *Facilitators or barriers to behavior change* (n=72), compared to those about *User experience* and *Measures of change* (n=132), demonstrates the weight of inquiry in research toward the latter. While psycho-social factors influence the use of mHealth, this review shows that there are relatively few assessments of these forces in mHealth studies. For example, by inquiring about motivation as well as intention and external support, studies could provide a greater understanding of not just how much something has changed after a study, but also why. We need to understand the context, i.e. motivations, facilitators and mindsets, to which we are introducing mHealth interventions to understand what makes mHealth-use relevant and sustainable. Inherent factors within patients and HCPs, such as perceived roles and responsibility within chronic health care, influence how these users choose to –or not to- use an mHealth intervention. By including questions that address psycho-social factors, in addition to those that measure objective or quantitative pre-post factors, we can begin to explain when, how and why users choose to engage with mHealth in such ways that do –or do not- lead to sustainable health behavior change.

5. Conclusion

This review has demonstrated that while the qualitative questions asked in mHealth intervention studies do cover essential information, e.g. usability, there is a gap in our understanding of how and why users' choose to use mHealth interventions. By leveraging underutilized psycho-social factors, we can better understand the reasons for mHealth-use and study outcomes. Future studies could then tailor interventions to address end-user needs and more effectively optimize these technologies to facilitate health behavior change.

Social Robots for Elderly Care: An Inventory of Promising Use Cases and Business Models

Somaya Ben ALLOUCH^a, and Lex van VELSEN^b

^a*Amsterdam University of Applied Sciences, Amsterdam, The Netherlands*

^b*Roessingh Research and Development, Enschede, The Netherlands*

Abstract. This paper discusses a study that aimed to elicit promising application areas and potential business models for social robotics in healthcare. For this goal, we conducted focus groups with care professionals and the management of elderly care organizations in the Netherlands and Germany. Three use cases were mentioned as the most promising: the robot as a ubiquitous aid, the robot as a helper in the room, and the robot as a guide. Finally, we discuss the implications of the medical device and privacy legislation for these three use cases.

Keywords. Social robots, healthcare, use cases, elderly care, business models, GDPR, legislation

1. Introduction

It is well known that large parts of Europe, including the Netherlands, must address growing challenges in the current health system. The number of elderly people is increasing, as is their demand for care, and Europe is struggling with a shortage of professionals in the care sector to cope with the increasing demand. To keep healthcare costs under control, it is important for older people to live independently at home for as long as possible and, where possible, to support professionals in their daily work activities to reduce the high workload. Social robots, which can be defined as robots that aim to foster “close and effective interaction with a human user for the purpose of giving assistance and achieving measurable progress in convalescence, rehabilitation, learning, etc.” [1, 2], can be of value here. For example, they can monitor the health of elderly adults and help improve or maintain elderly adults’ physical and cognitive health (e.g., by offering personalized training programmes) [3]. In addition, social robots can also be used by professionals for tasks and activities that they feel are less urgent. In this way, they can focus on the clients who need care at that moment.

The use of social robots for healthcare purposes is far from commonplace in Europe due to various issues, such as the current reimbursement system for the use of robotics in healthcare, a lack of familiarity with the possibilities of social robotics among healthcare professionals, and a lack of clarity among companies as to how they can and may use robots in healthcare institutions. This reluctance among companies is fuelled by uncertainty about privacy legislation and medical device regulations regarding robotics. To gain better insight into the role that social robotics can play in

elderly care, we created an inventory of promising use cases, potential business models and relevant regulations. To this end, we conducted a range of focus groups among care professionals and care management in the Netherlands and Germany.

2. Methods

To identify promising use cases for social robots in elderly care, we conducted three focus groups with care professionals. Two focus groups took place in the Netherlands (with six and seven participants) at care organizations that focus on elderly care in the broadest sense of the word (home care, nursing, rehabilitation, etc.). A German focus group included five participants and was held at a rehabilitation centre that treats many elderly people. The focus groups consisted of the following parts:

- Introduction of participants and the goal of the focus group;
- Moments of frustration during a workday. Here, we inventoried problematic situations about working in elderly care;
- Improvement for work activities. Here, we inventoried which solutions the participants saw for improving the problematic situations;
- Introduction of social robots. At this point, we introduced social robots and explained to the participants what they are and can generally do;
- Potential roles for social robots. Participants were asked to indicate for what type of activity (consultation, diagnosis, monitoring, training, social, lifting and carrying people or things) they thought social robots were most useful;
- Promising use cases. Together, participants looked at the problematic situations and linked these with the potential roles for social robots to identify the most promising use cases.

To uncover potential business models for the use cases we identified in the first round of focus groups and to discuss relevant legislation. We conducted focus groups with the management of elderly care organizations. Two focus groups were held with a Dutch ($n=6$ in both focus groups) institution and one with a German ($n=4$) healthcare institution. The employees who participated in this focus group consisted of Information and Communication (ICT) managers, policy-makers, training managers, innovation and care policy-makers, purchasing managers and members of the management team. During these focus groups, we presented the results of the sessions with care professionals, repeated the introduction of social robots and the inventory of potential roles, and added discussions on potential business models, implementation strategies, and applicable legislation.

3. Results

3.1. Care Professionals

During the focus groups, the participant ranked the six potential roles for social robots. They are as follows (from high to low): 1) social interaction; 2) monitoring; 3) training; 4) lifting and moving; 5) consultation; and 6) diagnosis. The professionals indicated that they would like to use the robots so that the client has “someone” to talk to because they felt that they did not always have enough time for this activity due to tight

work schedules. They also indicated that they wanted to use the robots so that they could monitor and reassure clients. A third point was that the robots could help to train the clients. A robot could perform the right exercises more often and help motivate people to perform permanent exercises so that their health could improve. It was also mentioned that robots could be used for lifting and moving clients. Finally, it was mentioned that robots could make diagnoses, but the general tendency was that people can still do this better than robots and that healthcare professionals found this function the least attractive.

An exploration of possible application areas led to three scenarios that were widely supported by the various healthcare professionals and that can already be realized with the current technology:

The robot as a ubiquitous aid. This robot records questions from clients/patients (e.g., questions about daily activities, requests for help with nausea), prioritizes the importance of these questions and only forwards a question to a professional in case of high urgency (as healthcare professionals indicate that they are overwhelmed by all the care questions they receive). The robot can also pick up objects from the ground (such as cutlery). In this way, the robot can reduce the workload of healthcare professionals and remove uncertainty from clients/patients. This use case was particularly helpful in helping clients in the common room of a care facility.

The robot as a helper in the room. This robot can look into the home of a client when an alarm goes off to determine whether an alarm is false or not. The privacy of a client is unnecessarily harmed if a professional must enter the home/room of a client at night for no reason; such a situation can be avoided by using a social robot. The robot can also set up a speech connection between the client and the healthcare professional to discuss whether help is needed. Finally, the robot can provide spoken memories (for taking medication, help with a regular daily routine). This reduces the workload of the professional, reduces unnecessary help and improves the daily rhythm of the client.

The robot as a guide. This robot reminds patients who are staying in a healthcare facility about an upcoming appointment (e.g., with a physiotherapist) and guides them to the location of this appointment (currently, patients often get lost, which is detrimental to the care provider's timetable and efficiency). In addition, the robot can guide visitors to their destination within a healthcare institution.

3.2. Management

The most important result of these focus groups was that with regard to a sustainable business case of social robots in healthcare, the majority of the participants stated that social robots should, above all, have added value for clients rather than for care professionals. The great potential that the participants saw to use social robots for patients and employees was partly reduced by many unresolved questions about the use of social robots. These questions relate to data security and liability, reliability during use by patients, quality management and integration into existing structures in the healthcare system, as well as their financing.

Interestingly, themes such as the replacement of personnel by social robots and the possible lack of human contact did not play a major role. The participants saw the possibility of relieving staff both physically and organizationally (e.g., taking over logistic tasks by a robot, completing customer surveys) and giving them more time to stay in touch with the patients.

An important barrier mentioned by participants was that they encounter problems with the implementation and use of social robotics in relation to relevant legislation and regulations, such as those that have been established for medical devices. The three user scenarios that emerged from the focus group with professionals were then used to map out relevant legislation and regulations with regard to social robots and current legislation and privacy.

3.3. Medical Device and Privacy Legislation

In the discussion with management, two main sets of legislation were discussed: the Medical Device Regulation (MDR) and the General Data Protection Regulation (GDPR). The MDR states that a device should be considered a medical device when it is used for one or more of the following purposes (limited to those that are applicable to the case of social robotics): the diagnosis, prevention, monitoring, prediction, prognosis, treatment or alleviation of disease; and/or the diagnosis of, monitoring of, treatment of, alleviation of, or compensation for an injury or disability. Key in this definition is the so-called ‘intended use’, which is stated by the manufacturer. For medical devices, the use of the device for purposes other than the intended use is prohibited, since the CE certificate is not valid when the device is not used for the intended purposes. Only in specific cases, e.g., during clinical investigations, may a device be used for purposes other than those intended, but only when this is allowed by the manufacturer.

Research into these regulations shows that robots in use cases 2 and 3 are not regarded as medical devices. After all, the robot is a means of communication (use case 2) or does not have a medical purpose (use case 3). The robot in use case 1 is regarded as a medical device, class IIa, but depending on the monitoring purposes for which the robot is used, it can also be classified as class IIb or III.

The General Data Protection Regulation (GDPR) has been in force in Europe since 25 May 2018 [4, 5]. A user of the robot (or its representative) will have to give permission for the storage and use of personal data. In addition, the supplier must provide information about the reasons for storage, how the user can influence this, and how data are exchanged. Since users will also be profiled in use case 1, the supplier will have to explain why this is done and in what way and will have to give the user the option not to use these profiling services. For use cases 2 and 3, the same rules apply (although the rules on profiling will probably not apply).

4. Discussion

In this study, we have identified the most promising use case for using social robots in elderly care and have explored potential business models. These use cases are the robot as an ever-present helper, the robot as an aid in the room, and the robot as a guide. Next, we mapped potential business cases with elderly care management and discussed related legislation. This study is one of the first to take such an approach towards social robots in elderly care or even healthcare. However, insights such as these are instrumental for developing social robotics applications, implementation plans, and exploitation plans and, as a result, are a prerequisite for successful and durable implementation.

As in any study, ours has some limitations. First, the identified use cases and insights regarding potential business models are highly influenced by the Dutch and German context and care systems. Therefore, caution should be exercised when generalizing these results beyond these two countries. Finally, elderly care has an extremely wide range of functions, involved professionals, and care protocols. To cover all of them in a study such as this one is impossible. It is possible that we missed a potential use case. However, we feel that we have generally identified the most important use cases.

The use of social robotics can be of tremendous added value for healthcare practice. However, we will have to experiment, deploy and collaborate more frequently and in an increasingly informed way, especially with professionals and clients, to determine the contexts in which the use of social robots in the healthcare sector will be most sustainable.

The Digital Transformation of Patient-Reported Outcomes' (PROs) Functionality Within Healthcare

Jeppe ERIKSEN^{a,1}, Pernille BERTELSEN^b, Ann BYGHOLM^c

^{a,b}Department of Development and Planning, Aalborg University

^cDepartment of Communication and Psychology, Aalborg University

Abstract. This paper elucidates how the functionality of Patient-Reported Outcome (PRO) has evolved due to its digital transformation. Hence, PROs traditional use within healthcare is described and compared to the application of electronic PROs (ePROs); leading to a discussion regarding PROs functionality. The literature included in this paper stems from a systematic scoping review. The digitalization supplements former functionalities of PRO by enabling timely, accessible, systematical and progression oriented data; however, further improvements are necessary to enhance PROs application in current healthcare.

Keywords. Patient-reported outcome, PRO, digital mediation, ePRO and PROs functionality

1. Introduction

Patient-reported outcomes (PROs) are increasingly used in current healthcare due to their multidimensional functionality, among other things, made possible by the digitalization of PRO. An alteration in the use and mediation of PROs, which have shown to be feasible [2], also as part of clinical practice [1].

A commonly used definition of PRO was coined by the American Food and Drug Administration (FDA) in 2009, stating that PRO is: “Any report of the status of patient’s health condition that comes directly from the patient, without interpretation of the patient’s response by a clinician or anyone else” [3].

Traditionally, PRO-questionnaires was used to test the effect of new drugs on patients, and as aggregated data targeted research purposes [5]. However, more extensive use of PRO in clinical practice is currently gaining ground within healthcare. Thus, data is no longer preserved clinicians and scientist, since PRO-data now is expected to inform, include and actively engage patients in managing their own disease [6]. Therefore, PROs integration into clinical practice has altered its current purpose and functionality [7].

Hence, this paper provides an overview of PROs functionality pre and post its digitalization and discuss ongoing challenges.

2. Method

The literature included in this article stems from a systematic scoping review regarding the link between PRO and patient participation. A comprehensive review,

¹ Corresponding Author: je@plan.aau.dk.

which therefore also provides an overview of PROs functionalities and digital transformation. Hence, the articles in this paper are a selective extraction, included if they pertain to PROs functionality pre or post its digital mediation.

The publications were identified using the following databases: PubMed, Embase, CINAHL and Scopus. The objective was to identify associations between patient participation and PRO. When conducting the search, the word 'patient-reported outcome' was included every time, and then combined with search words covering either: 'patient recognition', 'patient participation' or 'patient empowerment'. Exclusion criteria pertained to studies regarding primary care, traditional research studies where PRO was used as a secondary endpoint and studies where children were the subject field. Inclusion criteria consisted of articles covering, e.g. PROs used at hospitals or outpatient clinics, articles examining PROs effects, directly as well as indirectly. This strategy resulted in 6,895 articles; decreasing to 4,343 after duplicates had been removed. After reading and sorting the abstracts 256 articles were fully read and assessed for eligibility [8]; hereof, 27 articles are included in this article.

3. Applications of PRO

3.1. PROs functionality

Originally, PRO was used for group-level research and medical research, as supplement data/secondary outcome measures in clinical trials, e.g. in randomized controlled trials (RCT) studies, testing new drugs and evaluating the comparative effectiveness of healthcare interventions. Thus, the collection of PRO-data established a systematic approach when eliciting patients perspective on what mattered to them regarding their health status, their experiences pertaining to adverse effects, side-effects, comorbidity, and the burden of illness or treatment [5][9].

Therefore, the integration of PRO means that the evaluation of treatment no longer merely is based on objective criteria and physicians assessments, but on patients' perceptions and experiences as well [4]. A shift of focus in healthcare interventions, emphasizing the importance of patients health-related quality of life (HRQoL) to complement more traditional survival measures [10].

3.2. ePROs functionality

Furthermore, the digital transformation of PRO may enable new functionalities.

Firstly, when PRO is digitally mediated it allows real-time monitoring of patients and timely-data becomes available during patient-clinician consultations; potentially, leading to tailored patient management, improved decision making, more accurate diagnosing and better treatment [11].

Secondly, accessibility of PRO-data changes when digitalized as it enables patients to access data from at home; allowing them to follow their disease progression systematically over time. Therefore, the completion of ePRO-questionnaires potentially initiates a learning process as patients are confronted with issues pertaining to their condition; thus, PRO-data might empower and engage patients [12]. This feature, coupled with patients opportunity to track their disease progression over time and, e.g. set disease-related goals, are focal reasons why PRO-data is perceived as a self-management tool [13]. Thus, ePROs increased accessibility potentially improves patient

participation and self-monitoring as part of patients everyday life [13][14]. Moreover, ePROs might also affect patients’ ability to engage more actively in conversations with healthcare professionals; potentially, enhancing shared-decision making in clinical practice [11].

Furthermore, improved accessibility also means that PRO can be used as a coordination tool as it supports organizational information flows on both a vertical and horizontal level. In other words, the digitalization of PRO potentially enables healthcare teams and providers on different organizational levels to share data. As a result, stakeholders are able to base decisions on timely data, while patients’ avoid having to complete similar questionnaires over and over again, as they progress through the healthcare system [7]. However, this feature of PRO-data arguably relies heavily on adequate digital infrastructures [15] and regulations like, e.g. GDPR.

Thirdly, the systematic digital collection of PRO-data offers stakeholders an opportunity to plan and execute healthcare based on population data; exemplified by the value-based healthcare (VBHC) approach, where the reduction of health care costs and efficient use of resources are central aspects [16]. Thus, VBHC, via the use of digital PRO-data, might enable benchmarking, reimbursement and accountability of healthcare providers based on values pertaining to patient preferences and economic efficiency [14]. Moreover, this application of PRO-data might be used to improve systematic knowledge sharing among healthcare providers [14].

Lastly, PRO, as part of a triage system, is an example of a more recent application. The system is based on algorithms, which sorts patients into different categories (green, yellow and red) according to their health status; subsequently, determining who needs to show up for a patient-clinician consultation. Hence, some patients are able to skip unnecessary routine consultations, which ensures that those patients who are in need of medical attention, are prioritized [17].

Table 1. PROs functionality on an individual and population level pre and post its digitalization.

Stakeholders ²	Functionality	Pre digitalization (PRO)	Post digitalization (ePRO)
C	Decision-making and treatment [11]	x	x
C	Diagnosing [18]	x	x
CP	Patient perspective [4][6]	x	x
CP	Shared-decision making (SDM) [6]	x	x
CI	Drug testing [19]	x	x
CI	Research [14]	x	x
CPM	Patient-centred healthcare [14][20]	x	x
CP	Communication/dialogue [13][20]	x	x
C	Screening [11][20]	x	x
CPM	Patient satisfaction [6]	x	x
P	Patient participation [6]		x
P	Self-management [6][13][14][17]		x
M	Health policy development [21]		x
CPM	Quality of care [1][14][20]		x
CM	Best practice [14]		x
CP	Adherence [6][15]		x
M	Reduce health care costs/efficient use of resources [22]		x
CM	Triage system based on algorithms [17]		x

² Stakeholder terminology: C – clinicians, P – patients, M – managers/politicians, I -industry

P	Patients goals [15]	x
M	Monitor population health/preventive tool [7]	x
C	Monitoring and patient management [22]	x
M	Value-based healthcare (VBHC)/ Benchmarking/Reimbursement/ Accountability [16]	x
CM	Coordination tool/ Interdisciplinary/multidisciplinary communication [20]	x
P	Patient Empowerment [23]	x
P	Self-monitoring [24]	x

Table 1. Demonstrates how the digitalization of PROs has altered its functionality. Thus, PRO has changed from mainly being a tool used by clinicians and industry for research and drug testing, to now also being a tool used by patients, healthcare managers and politicians, e.g. facilitating systematic patient participation, patient management and VBHC.

4. Discussion

The paper elucidates how the digitalization of PROs has changed their functionality and purpose. However, even though the digitalization has improved and innovated PROs functionality, certain issues pertaining to the application and implementation of PROs still persist.

Therefore, even when ePROs, in some cases, might increase data accessibility, the use of PROs in healthcare can also exclude particular groups of patients. Thus, low health/eHealth literacy [25][26] and lack of technological access [19][22][27], are factors which potentially exclude patients; subsequently, creating a barrier towards patient participation. Hence, clinicians and managers need to be aware of the patient burden PROs might entail [22][27], to make sure that the use of PROs enables patient empowerment and not turns into patient work [28].

Furthermore, it is essential to make sure that PRO-data is actionable [6] and actually used in clinical practice since this is not always the case [29]. Therefore, to secure the use of PRO-data in clinical practice PRO measures need to be clinically relevant [22][29], and clinicians should be trained regarding the application and interpretation of PRO-data [29][30]. Whereas, on an organizational level, attention to how workflows are affected [27] and whether sufficient time is allocated for meaningful use of PROs [30] is needed.

Hence, even after PROs digital transformation, there is still a lot of work to be done to make sure that PRO fulfil its potential, which is why further research within this area is recommended. However, as the overview in table 1. Demonstrates, ePROs have the potential to further a more personalized and actively engaging approach in healthcare.

The Effect of Patient Accessible Electronic Health Records on Communication and Involvement in Care - A National Patient Survey in Sweden

Jonas MOLL^{a,1} and Hanife REXHEPI^b

^a*Centre for empirical research on information systems, Örebro University, Sweden*

^b*Department of Information Technology, University of Skövde, Sweden*

Abstract. During recent years, patient accessible electronic health records (PAEHRs) have been implemented nationally in Sweden, as well as internationally, as a means of supporting patient engagement and shared decision making. Few studies have, however, investigated the long-term effects of PAEHRs on communication with care professionals and involvement in care. The national survey study presented here, answered by 2587 patients in Sweden, focuses on these aspects specifically. The results show that the Swedish PAEHR system *Journalen* has had a positive impact on communication with care overall (84% agree or strongly agree with that communication with medical staff has improved), but only 31% agree or strongly agree with that the content of the PAEHR is discussed with care professionals. *Journalen* also seems to have a positive impact on involvement in care, but the results are mixed when it comes to effects on shared decision making.

Keywords. eHealth, patient accessible electronic health records, communication, patient involvement, national survey

1. Introduction

The communication between clinicians and their patients is a fundamental component of clinical practice and is essential for achieving quality healthcare [1][2]. In recent years, a growing emphasis on patient autonomy, patient-centered care and patient participation has further exemplified the importance of effective doctor-patient communication [1]. Prior research on patient complaints has shown that poor attitudes and poor quality of information provided are the most commonly identified communication errors made by doctors [1]. In Sweden, a new legislation - the Patient Act or Patientlagen - was approved in 2015 with the aim to strengthen the patient's position and rights in healthcare. The patient act covers areas such as accessibility, patient participation, information provided by healthcare professionals and consent. However, studies have reported that the act has had limited impact on healthcare [3]. Patients are still feeling poorly informed regarding their

¹Corresponding Author: Jonas Moll, E-mail: jonas.moll@oru.se.

test results, treatment options and management and less involved in their own healthcare [3]. These results are worrying as there is a growing recognition that patients can participate more actively in decisions regarding their own care when they are provided with information [4] [5]. Moreover, the WHO in their policy framework for Health 2020 [6] and the Swedish government [7], like other governments worldwide e.g. England [8], advocate and endorse the need for healthcare organizations to support patients being active participants in their own care. Therefore, a lot of effort has been put into the development of new technologies for health (eHealth) with tremendous potential for promoting patient participation, enhancing information-sharing and communication between patients and healthcare professionals and improving health outcomes [9]. An example of this type of a service is to provide patients with easy access to their electronic healthcare record (EHR), so called patient accessible EHR (PAEHR), through secure eHealth services. The overall goal of PAEHR is to improve communication between healthcare professionals and patients, ultimately increasing patients' participation in care and improving the shared decision-making process [10]. Two of the most well-known examples of PAEHR are OpenNotes in USA [5] [11] and MyUHN Patient Portal in Canada [12]. A similar service was launched in 2012 in Sweden, when Region Uppsala gave all citizens over 18 years of age online access to their EHR through the eHealth service *Journalen*. This service was eventually launched as a national system in Sweden, accessible through a national patient portal. However, PAEHR are still accompanied by major concerns from healthcare professionals, who stress that online access might lead to an increased workload, privacy risks and cause patients to worry [13] [14]. Studying and understanding if and how PAEHR affects communication between healthcare professionals and patients is important as communication is essential for the quality of healthcare. Moreover, patients use of and attitudes toward PAEHRs has up until today mostly focused on general attitudes to the prospective introduction of such eHealth services. Hence the aim of this paper is to investigate the effects of *Journalen* on communication with healthcare professionals and the patients' involvement in their own care.

2. Method

A national patient survey was made available through a link on the login page of the Swedish PAEHR system *Journalen*. The survey was ethically approved by the Regional Ethical Review Board in Uppsala (EPN 2016/129). The survey, which was open for all patients accessing *Journalen* during the five months period June-October 2016, included questions on several topics such as attitudes and reactions, access to and use of information, personal health, usage behavior, information literacy and information security. The questionnaire included questions with various response options (5-point Likert scale, multiple choice, and free text form). In total, 2587 patients responded to the survey, giving a response rate of 0.61% (2587/423141). Moll et al. [15] presents the study design in more depth and some overview results from the survey. Even though the results from two of the questions in this study (a and d) are also presented in the overview article (Moll et al. [15]), the contexts in which those results are presented are different - while this paper focuses on communication and involvement the overview article focuses on general usage behaviours and usage patterns. Only completed questionnaires have been analyzed, as the answers were stored in the database only when the respondent chose to

submit on the last page. This paper covers two important themes from the survey, and the debate about eHealth systems in general – namely (1) communication with healthcare professionals and (2) involvement in care. SPSS 25 was used for all analyses.

3. Results

When it comes to gender distribution among respondents, the majority (1629/2587 = 63%) of the respondents were women, which corresponds well with official data on usage of the system. The majority of the respondents (61 %) also had an educational background of at least three years in higher education.

3.1. Communication with clinicians

Results related to questions on communication are presented in Table 1. The questions/statements are: (a) *The PAEHR improves communication between medical staff and me*; (b) *To take part of the patient information via Journalen has affected the relationship with health care system positively*; and (c) *I discuss the content of Journalen with medical staff*. As can be seen from the table, the majority of the respondents believe that access to *Journalen* has improved the communication with medical staff and the relationship with healthcare overall. On the other hand, the content of *Journalen* does not seem to be discussed with medical staff to any large extent.

Table 1. Results regarding PAEHR in relation to communication. The highest value for each question is indicated with bold face.

Question	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
a	1418 (56%)	705 (28%)	280 (11%)	67 (3%)	55 (2%)
b	865 (34%)	781 (31%)	656 (26%)	95 (4%)	118 (5%)
c	255 (10%)	511 (21%)	448 (18%)	329 (13%)	945 (38%)

3.2. Involvement in care

Results related to questions on involvement in care are presented in table 2. The questions/statements are: (d) *I use Journalen to become more involved in my care*; (e) *Information in Journalen had a positive impact on the ability to work together with medical staff making decisions about care and treatment*; (f) *Information in Journalen had a positive impact on the ability to follow the prescription of treatment*; and (g) *Information in Journalen had a positive impact on the ability to take own steps to improve health*. As can be seen in the table the majority of the respondents strongly agree or agree with all statements, even though there is a rather high portion of neutral respondents when it comes to shared decision making and self-care.

4. Discussion and Conclusions

The results presented in this paper show how patients experience that their communication with healthcare professionals and their involvement in the care process has been

Table 2. Results regarding PAEHR in relation to involvement in care. The highest value for each question is indicated with bold face.

Question	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
d	1372 (56%)	651 (26%)	283 (12%)	57 (2%)	107 (4%)
e	571 (24%)	645 (27%)	785 (32%)	186 (8%)	215 (9%)
f	848 (35%)	712 (29%)	575 (24%)	117 (5%)	170 (7%)
g	652 (27%)	681 (28%)	725 (30%)	139 (6%)	207 (9%)

affected by PAEHR. The results are important for our understanding of the effects of PAEHR for patients, since they are based on the first large follow-up study conducted several years after launch of *Journalen* in Sweden. Earlier studies, like the interview study with cancer patients conducted by Rexhepi et al. [16] one year after launch, rather reflects short-term effects. It is clear that the majority of the respondents believe that access to information from PAEHR allows them to communicate more effectively in conversations with healthcare professionals regarding their own care. One explanation for these results may be that access to test results and information about care plan, treatments etc from PAEHR can, as reported in studies such as [17] and [18], improve the patients' understanding of their medical condition. Hence, it is possible that the patients' understanding of their illness affect their ability to engage in meaningful conversations with the physician. Moreover, as a result of accessing information from the PAEHR, the majority of the patients also report an improved communication and relationship with healthcare professionals.

Furthermore, a significant amount of patients reported that they use *Journalen* to become involved in their own care. However, when it comes to involvement in terms of increased ability to engage in self-care and shared decision making, the results are not as positive. The reasons are difficult to find in a survey, however engaging in e.g., shared decision making is a two-way-process where a clinician and patient jointly participate in making a medical decision [19]. If patients do feel that their opinions are not valued, they may be less inclined to engage in the meaningful conversations needed for effective shared decision making. Hence, provision of information alone from PAEHR will not automatically result in patients engaging in shared decision making. Instead, healthcare professionals must incorporate patients into the decision-making process. Future studies will be needed to look more closely at the association between note reading and shared decision making. Furthermore, despite ethical principles and legal requirements to engage patients in their own care, some patients may not want to be active participants. It is however vital that clinicians assess and understand the role each patient wishes to play in his or her care. Moreover, the majority of the respondents also strongly agree with that *Journalen* makes it easier for them to follow prescriptions, which is in line with earlier studies in the area [20]. The results also show that the contents of the PAEHR is not discussed to any large extent during the patient meeting. This is not surprising considering the resistance shown by the healthcare professionals, especially physicians and their trade union, in Sweden [14]. However, given that patients, over all, perceive PAEHR as positive and important it is of high relevance to study why the contents of PAEHR are not discussed with patients and how they can be integrated into the patient meeting.

Abstract. PROMISE (Personal Medical Safe) was a German research project which aimed to provide the responsibility of genomic data to the patient via a mobile app. The patient should accept or decline study requests to use his/her genomic data via the app. In the evaluation of the app the experiences with mobile health as well as the opinion on being the genomic data manager were measured. Furthermore, the test patients were asked about their opinion and their concerns on the PROMISE app. Most of the 19 test patients were aware of the high sensibility of genomic data and thought that the PROMISE app was a suitable solution. The largest part found it good that they were the responsible data owner. However, several participants also found it important to have a permanent contact person when it comes to questions on inquiries or the app.

Keywords. Personalized medicine, genomic sequencing, patient empowerment, technology acceptance

1. Introduction

In today's healthcare there is a shift to empower the patient from being a mere recipient of medical treatments to being an active partner in the own healthcare process [1]. It has been shown that patients that are willing to actively participate potentially can achieve better health outcomes than more passive patients [2-4]. In Germany statutory health insurances are obligated to provide electronic health records for their patients starting in the year 2021; and consumer-based health apps can be prescribed by physicians to their patients in the future [6].

A big trend in current healthcare is the so-called personalized medicine which takes individual factors into account and offers therapeutic measures individually tailored for each specific patient [7]. This includes the use of genomic data to develop

1 Corresponding Author: E-mail: lena.griebel@fau.de

the best therapy options. Different institutions also access and use anonymized genomic patient data for research purposes. Until now patients however mostly have no or very limited access to their genomic data which have been collected in the clinical setting. In the German BMBF funded (German Federal Ministry of Education and Research) research project PROMISE DS (Personal Medical Safe) the patient should be an active partner in this genomic medicine assuming that he or she is indeed able and willing to. Studies have shown that patients in general want to be involved in new health technologies [8, 9] but that it is necessary to assess the patients' preferences towards engagement strategies beforehand [10].

PROMISE DS developed and provided an infrastructure and patient app, which allows encrypted storage of genomic data in the background and patient management of access to this data in the foreground. The objective of our companion study was to evaluate patients' attitude towards and acceptance of this innovative technology. We wanted to gain insights into the potential genomic data managers' point of view and thus learn for the further development and deployment of such a new and innovative technology. The main research questions were:

1. How much experiences have the patients with apps and health apps?
2. What is the knowledge of the patient regarding genomic testing and what are the patients' concerns?
3. What do patients think of the PROMISE app?
4. What is the patients' general opinion on being the genetic data manager?

2. Methods

We selected test patients to use the PROMISE app over four months. All the test patients were cardiomyopathy patients recruited at Heidelberg university hospital. Cardiomyopathy is a disease known for its genetic predisposition. The genomes of all patients in our study have been sequenced before.

We included patients with a minimum age of 18 years with a medical indication for genetic testing and regular access to an Android-based smartphone. Patients who fulfilled the inclusion criteria were given an information sheet about the study and had to give their informed consent. The treating physician helped them to install the PROMISE app on their personal smartphone. It was made clear that the app would not offer medical advantages for the patient but the focus of the project was to learn about possible ways of designing an app with the patient as genomic data manager. Over the course of four months the patients received 12 simulated queries through the mobile application. There were no real customers; the requests have been developed by project members. The inquiries were designed to look as if they originated from hospital researchers, university researchers and commercial companies. The patient had the options 1) to accept, 2) to decline or 3) to ignore the request. Before and after the use of the PROMISE app the patients each fulfilled a questionnaire consisting out of closed questions in a pen-and-paper-approach. The questionnaires were designed on the basis of self-developed questions and already existing tools such as the questionnaire on patients' perspective on pharmacogenetics testing by Rogausch et al [11]. Supplementary to the paper-based questionnaires interviews were performed at the second time point to further assess the opinion toward genetic testing. The evaluation

was performed with 19 patients at both time points – the interviews with 11 participants.

3. Results

3.1 App Using Experience and Knowledge on Genomic Testing

We asked the participants about their current use of apps and health apps.

The largest part said that they used apps on a daily basis (14 of 19). Nevertheless, ten of 19 participants stated that they never use specific health apps, five used health apps very rarely and only each two persons stated to use health apps on a daily or weekly basis.

The test patients were asked to self-assess their knowledge regarding technical terms such as “gene”, “genetics”, “genome” or “pharmacogenomics”. Whereas the knowledge on the terms “gene” and “genetics” was rather good, the patients assessed their knowledge on “pharmacogenomics” very low. 15 out of 19 test patients said after the test use of the PROMISE app that they are aware or very aware that genetic data are particularly sensitive; before they used the app also 13 patients agreed or fully agreed on that. In the interviews data security was as well revealed as a major concern regarding genetic testing.

Also the major part of the participants agreed or fully agreed that genetic information should only be stored when high safety precautions are met (15 agreed/fully agreed before the test use; 18 agreed/fully agreed after the test use). Most participants (14 before the test use, 18 after the test use) stated that they thought that the safety concept of PROMISE protected their privacy well or very well.

3.2 Opinion on the PROMISE App

After the test use of PROMISE most participants said that they found the (simulated) study inquiries very interesting or interesting (79%), 21% were unsure about it. None of them did find the inquiries disruptive in their daily life.

Also after testing PROMISE, 10 persons were afraid to falsely accept inquiries due to misunderstanding them, only three to falsely decline inquiries. In the interviews nearly every participant stated that the PROMISE app was a good idea. Several participants also mentioned that it was very important to have a permanent contact person to ask when it comes to difficulties or uncertainties when using the PROMISE app.

3.3 Opinion on Being the Data Manager

Most of the test persons found it good or very good (15 before and 18 after the test use) to own a safely stored copy of their own genetic data. Before the test use four persons were unsure, after the test use only one person was unsure about this question. Also in both time points most participants stated that they were satisfied or highly satisfied with being in control over the use of the genetic sequence data (13 before, 17 after).

Nevertheless, 5 resp. 4 persons said that they were afraid of being the responsible person for the genetic sequence data.

4. Discussion

Even though the participants stated that they used apps in general very frequently, almost no one used health apps frequently. The general self-assessed knowledge on genomics and related terms was relatively low. Most test persons saw genetic data as especially sensitive and in need of high protection but also found the security concept of PROMISE convincing. Most participants were interested in the simulated inquiries and found them non-disruptive. They were more afraid to falsely accept study inquiries than to falsely decline study inquiries.

Owning a personal copy of the genomic data was found good or even very good by most of the participants. Also, most persons were satisfied with being in control over the use of the data. Besides the fact that the largest part of participants was not afraid of it, it has to be taken into account that several persons indeed were afraid of being the only data owner.

5. Conclusion

In our small study setting it got clear that data security plays an important role for the data-managing users. Further we might conclude that the layperson users would need support when it comes to the usage of technical/medical terms and scientific concepts in study inquiries, e.g. by a permanent contact person such as their treating physician. Also the test users were not familiar with the use of health apps. In general one might say that the users should not feel overtaxed by their responsibilities.

Although the findings of our study are not representative due to the small number of participants they nevertheless show that medical laypersons are indeed interested and willing to be the data manager of personal genetic data but that electronic services supporting them should be designed very thoroughly regarding their comprehensibility and data security and that a “real” contact person would be important.

Towards a Highly Usable, Mobile Electronic Platform for Patient Recruitment and Consent Management

Daniel ROBINS^{a1}, Rachel BRODY^a, In Cheol JEONG^a, Irena PARVANOV^a,
Jiazhen LIU^a, and Joseph FINKELSTEIN^a

^a*Icahn School of Medicine at Mount Sinai, New York, NY, USA*

Abstract. This study seeks to assess usability and acceptance of E-Consent on mobile devices such as tablet computers for collecting universal biobank consents. Usability inspection occurred via cognitive walkthroughs and heuristics evaluations, supplemented by surveys to capture health literacy, patient engagement, and other metrics. 17 patients of varied ages, backgrounds, and occupations participated in the study. The System Usability Scale (SUS) provided a standardized reference for usability and satisfaction, and the mean result of 84.4 placed this mobile iteration in the top 10th percentile. A semi-structured qualitative interview provided copious actionable feedback, which will inform the next iteration of this project. Overall, this implementation of the E-Consent framework on mobile devices was considered easy-to-use, satisfying, and engaging, allowing users to progress through the consent materials at their own pace. The platform has once again demonstrated high usability and high levels of user acceptance, this time in a novel setting.

Keywords. electronic consent, usability inspection, patient engagement, mobile app

1. Introduction

The E-Consent platform has matured through multiple iterations to capture patient consents for research studies in a highly usable way. Its central premise is to deliver interactive multimedia content that enhances patient engagement and education relevant to a study. Essentially, research staff just upload an approved informed consent and multimedia into the system, which then reorganizes the materials and presents it to end-users in a simple and easy-to-understand fashion. The key component of this approach, however, is the interface: the interface must be intuitive for the target audience and exceptionally easy-to-use for optimal engagement. By utilizing an iterative development approach and collecting feedback from key stakeholders and subject matter experts, our team refined the user interface over numerous cycles. The overarching goal of this multifaceted project is to prospectively assess usability, patient engagement, and acceptance of the system across a multitude of settings.

Previously we demonstrated its highly usable interface and acceptance when implemented at a workstation-like setting [1]. This study represents the continued usability inspection performed on the most recent iteration of the system, while also extending the platform to mobile devices such as tablets with touchscreens.

¹ Daniel Robins, E-mail: Daniel.Robins@mountsinai.org.

2. Methods

2.1. System Design

As described in our previous studies, system design has been guided by the Cognitive Theory of Multimedia Learning; information is structured on learning principles accounting for working memory and cognitive load [2]. The user interface was informed by our multiple previous works to deploy tools aimed at improving health literacy and patient engagement [3][4], while also accommodating limited literacy or numeracy [5]. Lessons learned from these studies have led to a Table-of-Contents design for the main menu of the application. Complex information is organized into a series of smaller ‘chapters’. Each chapter is structured similarly, beginning with a video explanation (Figure 1) of a person who explains the section in plain language. Subsequent pages in the chapter feature a few sentences of text that reiterate and expand on the relevant content. One-question quizzes appear periodically, to reinforce specific concepts. The full consent form is available at all times and on all pages of the system via the ‘Consent Now’ link. In any event, the user is automatically presented with the full consent form and the option to digitally sign it (Figure 2) upon completing all chapters.

For this study, content was entirely in American English.

2.2. Study Design

The study was designed to evaluate the usability of the system on mobile devices by eliciting quantitative and qualitative feedback.

Participants were all patients at the Mount Sinai Hospital in New York, coming from clinics including primary care, specialty care, and employee health. Upon sitting down with a tablet computer, participants were given a packet of surveys, followed by instructions to complete 3 tasks, then an additional package of evaluations and surveys to record their feedback. The tablet computer included a touchscreen, a stylus, and a keyboard with trackpad, and it was preconfigured to display the Electronic Consent system on screen.

Surveys began with a sociodemographics form and the Rapid Estimate of Adult Literacy in Medicine (REALM). Participants then performed three tasks as part of the cognitive

Figure 1. Video introduction to a chapter

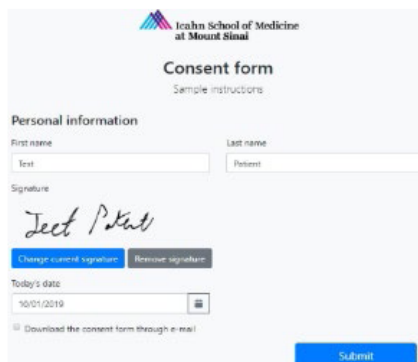

Figure 2. Signature Page

walkthrough. Afterwards, participants provided feedback on post-task questionnaires, a heuristics evaluation form, and the Process and Quality of Informed Consent for Clinical Research (P-QIC) form. A semi-structured qualitative exit interview completed the session.

The three tasks for the cognitive walkthrough could be completed with or without assistance from the research associate; if a participant needed help, this request was recorded. Task 1 instructed the user to complete all chapters of the educational module. Task 2 required users to complete the consent module and electronically sign the consent form. Task 3 asked users to complete an electronic version of the System Usability Scale (SUS).

After completing tasks 1 and 2, the participant was asked to grade each task on a scale of 1 (very difficult) to 5 (very easy) using a survey that included the following questions: 1) How difficult or easy was it to review the content and finish the sections? 2) How difficult or easy was it to answer the questions? 3) How satisfied are you with using this system to complete this task? 4) How would you rate the amount of time it took to complete this task? 5) Is the system visually appealing? 6) Is the system easy to navigate? There were also two open-ended questions that ask the participant to share any other feedback and to describe problems they might have encountered. Since Task 3 was simply an electronic version of the System Usability Scale, its post-task evaluation omitted questions that were not relevant to this section.

3. Results

Overall, 17 healthy adults at our clinics participated in this study at the end of Q3 2019. Average age of the participants was 33 years old ranging from 22 to 84 years; 12 participants identified as female, 4 identified as male, and one did not provide a response for this question. Participants reported a range of familiarity with informed research consent, from completely naïve users to experienced research coordinators. The average REALM score indicated a ‘High School’ level of health literacy.

Task self-assessment results are presented in Table 1 as average scores, with a score of 5 indicating highest satisfaction. For tasks 1 and 2, content difficulty ranged between 4.4 and 4.7, while question difficulty ranged from 4.7 to 4.8; task satisfaction varied from 4.2 to 4.3; ease-of-navigation ranged from 4.6 to 4.7. One participant required help to complete each of the tasks.

The heuristic evaluation’s highest mean scores were 4.7 for Visibility and 4.8 for Matching between the system and real world, whereas the lowest mean scores of 4.1 and 4.2 were associated with Help Documentation and Controls, respectively.

Table 1. Task Self-Assessment	Mean (SD)
Task 1: Complete Education Module	
Content Difficulty	4.7 (0.7)
Questions Difficulty	4.8 (0.7)
Satisfaction	4.2 (1.0)
Amount of Time	4.1 (1.2)
Visually Appealing	4.1 (1.0)
Easy to Navigate	4.6 (0.8)
Task 2: Complete Consent Module	
Content Difficulty	4.4 (0.9)
Questions Difficulty	4.7 (0.8)
Satisfaction	4.3 (1.1)
Amount of Time	3.9 (1.3)
Visually Appealing	4.4 (1.1)
Easy to Navigate	4.7 (0.5)
Task 3: Complete E-Questionnaire	
Satisfaction	4.8 (0.6)
Amount of Time	4.2 (1.2)
Visually Appealing	4.6 (0.7)
Easy to Navigate	4.9 (0.3)

System Usability Scores (SUS) were normalized in the usual fashion; SUS mean was 84.4, which corresponds with an ‘above average’ usability rating and places this system at greater than the 90th percentile.

The semi-structured qualitative interview captured feedback that described electronic consent on this platform as easy-to-use, engaging, and faster than paper.

4. Discussion

This mobile implementation of the E-Consent platform was well-received by users. The results of the cognitive walkthroughs are largely consistent with our previous work on this platform as well. Indeed, cognitive walkthroughs are well-suited for these evaluations as they effectively focus on how well a naïve / first-time user can perform a task without formal training [6].

The semi-structured qualitative interview yielded numerous actionable points and areas for improvement (Table 2).

The majority of participants reported that the interactive nature of the system improved their attentiveness to the content: “The interactivity helped me pay more attention to it”. Multimedia was also cited as a preferred feature. In the words of one participant, “I really like the videos, I prefer someone speaking to me rather than reading.” And another participant commented “Much better than reading it on paper. Definitely better to have this faster process. More concise is better.”

Although there was wide consensus that this interactive platform is preferable to paper, there was also agreement that human interaction should be maintained in some way: “Humans can build rapport”, “Human interaction is better”.

Regardless, users felt generally comfortable using the system on their own. One participant described an advantage of the interactive platform is that users “...can take their time...” Another described the milieu as “Very comfortable, simple, my parents who are not native English speakers could use it”.

Table 2. Semi-Structured Qualitative Interview, Summarized

Barriers	Advantages	Suggestions
Controls not visible enough	Simple to understand	Instructional video at start
Content too long	Easy to use	Progress bar
Too wordy	Interactive	Additional navigation buttons
Videos too long	Engaging	Subtitles for videos
Videos not descriptive enough	Move at own pace	Pop-up explanation over words
Need more human interaction	Faster than paper	Controls to adjust font size, color
Need paper supplement	Less waste	Streamline, reduce amount of content
Poor sound effect quality	Option to email	Audiobook feature / read-aloud text
Font size too small	Concise	Emphasize compensation of study
Images too small	Easy to navigate	Emphasize risks of study
		Option to mute audio
		‘Save and continue’ feature
		Real-time chat with human

Some participants were concerned about the intuitiveness of the interface for older patients. “Someone older or not familiar with tablets would have problems understanding and using it”. These concerns are reflected in the heuristics evaluations, which demonstrated lowest scores for ‘Help and Documentation’ and ‘Controls’. These scores may be due partly to the smaller display sizes on mobile devices; users may need to scroll the pages to find the buttons to navigate. This also indicates the need for a more obvious ‘help’ feature with instructions that describe this scenario.

Table 3. Heuristics Evaluation Means	
Heuristic	Average Score (SD)
Visibility	4.7 (0.6)
Match (system to real world)	4.8 (0.3)
Control	4.2 (1.3)
Consistency	4.6 (0.6)
Error Prevention	4.6 (0.6)
Recognition	4.6 (1.0)
Flexibility	4.5 (0.7)
Aesthetics	4.6 (0.9)
Error Recovery	4.6 (0.6)
Help & Documentation	4.1 (1.0)

Limitations of this study include the brisk sample size (17 patients) and the relatively high English literacy of those patients as evaluated by the REALM assessment. The mean REALM score was at the ‘High School’ level of literacy, which corresponds with participants’ English Proficiency; all users described their English proficiency as either ‘Excellent’ or ‘Good’. This limitation can be mitigated by broadening the patient base and expanding the study to more locations.

Next steps should be twofold: 1) further refine the interface for mobile devices based on feedback from this study, and 2) expand usability analysis and testing to include more diverse locations with a larger sample size. Electronic consent systems can conceivably reach into patient homes, and so the home setting is another logical next step for evaluation.

5. Conclusion

Formal usability inspection methods continue to generate actionable feedback, which has shaped the E-Consent platform into a highly usable framework for capturing electronic consents and engaging patients. The mobile iteration of this platform has now demonstrated a high usability rating with excellent levels of user-reported satisfaction. To enhance user-friendly design and engage as many patients as possible, future iterations of the product should account for mobile devices.

Towards a Lean Process for Patient Journey Mapping - A Case Study in a Large Academic Setting

Marieke SIJM-EEKEN^{a,1}, Jaqueline ZHENG^a and Linda PEUTE^a

^aAmsterdam UMC, University of Amsterdam, department of Medical Informatics, Amsterdam Public Health Research Institute, Meibergdreef 9, Amsterdam, Netherlands

Abstract. Hospital quality improvement initiatives that focus on the patient experience are increasingly gaining attention. One of the known improvement methodologies is patient journey mapping. Central to this methodology is the mapping process, resulting in a patient journey map: a visual presentation of the complete route a patient follows during all stages of a care trajectory and the patients emotional experience during this journey: the patient journey map. Currently, there is no standard approach on how to perform the steps in the mapping process and evidence is lacking on the most effective and efficient way. As a result, the adoption of the methodology by healthcare professionals is hindered, more time than necessary is spent on the mapping and a lot of significant variation exists in the quality of the resulting patient journey maps. The Lean methodology has a proven track of record to optimize and standardize processes. Hence, by performing a Lean analysis onto the patient journey mapping process, opportunities to optimize and standardize the process may be identified. This study aimed to assess the value of Lean methodology to optimize patient journey mapping in a hospital setting. Observations and interviews were performed to identify the process for patient journey mapping in a Dutch academic hospital. Lean was used to visualize the process and identify inefficiencies. An expert panel reviewed the improvement suggestions. We conclude that Lean can provide value for aligning different views on the process, for structuring the process steps and phases and for identifying optimization actions in the mapping process.

Keywords. Lean, patient journey, quality improvement, patient experience

1. Introduction

Understanding and improving how patients experience their care is increasingly recognized as one of the key components to successfully delivering high quality healthcare. *Patient journey mapping* is a relatively new and upcoming methodology used in hospital quality of care improvement initiatives to identify actions which could improve patient experience with the healthcare system [1]. In mapping a patient journey the experiences with and interaction between the patient and the healthcare providers in all stages of a care trajectory is explored. One of the foundations of this methodology is

¹ Corresponding Author: Amsterdam UMC, University of Amsterdam, department of Medical Informatics, Amsterdam Public Health Research Institute, Meibergdreef 9, Amsterdam, The Netherlands; E-mail: m.e.sijm@amsterdamumc.nl.

that patient experience is not limited to a visit to a specific healthcare provider. It includes the period before and after the visit, such as a visit to a GP, making an appointment for a hospital visit, waiting for the appointment to take place or looking up information in an (online) patient folder. How patients experience their care, is likely to change during this journey. Another central idea therefore is that patient experience is more than the rating that a patient gives to a healthcare provider, it also includes the feelings a patient experiences, like anxiety or uncertainty. The final result of the *patient journey mapping* is a visual representation of the patient journey: a map showing a timeline indicating all relevant interactions between the patient(group) and its healthcare providers (including interaction with their Electronic Systems) in combination with the different aspects of the patients' experience. The review of the patient journey by healthcare professionals subsequently leads to new insights on how healthcare services can better fulfill patient needs. This results in the identification of improvement actions [1,2].

Central to the methodology of *patient journey mapping* is the mapping process. Mapping a patient journey is a highly complex and time-intensive process that consists of multiple stages with interrelated activities to complete [2]. Currently, there is no standard approach on how to perform the steps in the mapping process and evidence is lacking on the most effective and efficient way. As a result, the adoption of the methodology by healthcare professionals is hindered, more time than necessary is spent on the mapping and a lot of significant variation exists in the quality of the resulting patient journey maps [3].

The Lean methodology has a proven track of record to optimize and standardize processes. Hence, by performing a Lean analysis onto the patient journey mapping process, opportunities to optimize and standardize the process may be identified. Because of the shortage in healthcare staff and financial limitations, it is important to work as efficiently and effectively as possible [4,5]. The objective of this study was to assess the value of lean in optimizing and standardizing the patient journey mapping process in an academic hospital setting.

2. Methods

First, the patient journey mapping process was observed and described in a Dutch academic hospital setting. This hospital was selected because of the availability of resources to participate in this research and its recent efforts to define a hospital-wide approach for mapping a patient journey. The scope of this study encompassed all activities from the moment a hospital department initiated a patient journey project till the delivery and review of a patient journey map. The observation was done by an independent Medical Informatician. A Lean tool for visualizing a process, a Swimlane diagram, was used to describe the mapping process. A Swimlane diagram documents process flows with different tasks per role and to provides insight into the order in which tasks are performed [6,7].

In the second step an expert panel consisting of a representative from the Communications department (who developed the approach and toolkit), an Operational Lead, a Medical Lead, a Lean expert (Master Black Belt) and a Medical Informatics junior researcher redesigned the mapping process based on the documented process in step one. In this step a Lean waste analysis was performed by a Lean expert. A Lean waste analysis is a tool which identifies suboptimal activities aiming at streamlining a process [8]. This step resulted in a proposal to optimize the process for mapping the

patient journey based on the applied Lean analyses. The value of applying Lean was then determined by the expert panel review on basis of accepted optimizations and insights gained the process. A Lean improvement was accepted by the expert panel if they considered it feasibility for implementation and if it fit the hospital's vision on patient journey mapping.

3. Results

The observations and interviews provided insight in the process for patient journey mapping in the academic hospital. The communications department took ownership on the mapping process and educated the departments that were supposed to apply it. In this paper this department is referred to as the Quality Improvement (QI) team. There was no top leadership pressure to create patient journey maps. The mapping process consisted of 2 workshops (a kickoff and a follow up workshop), actions to be taken by either the medical lead or operational lead and a toolkit to support the activities to follow. Tasks between the medical lead and operational lead were different depending on the way the specialty was organized. Use of the Swimlane diagram resulted in the identification of three phases with interrelated activities: the initiation, the data collection and the mapping phase.

Overall the Lean waste analysis provided sight on 11 improvements. The expert panel review accepted eight improvements and rejected three. Figure 1 shows the resulting Swimlane diagram. The rectangular boxes in Figure 1 represent activities. Each activity has detailed work instructions.

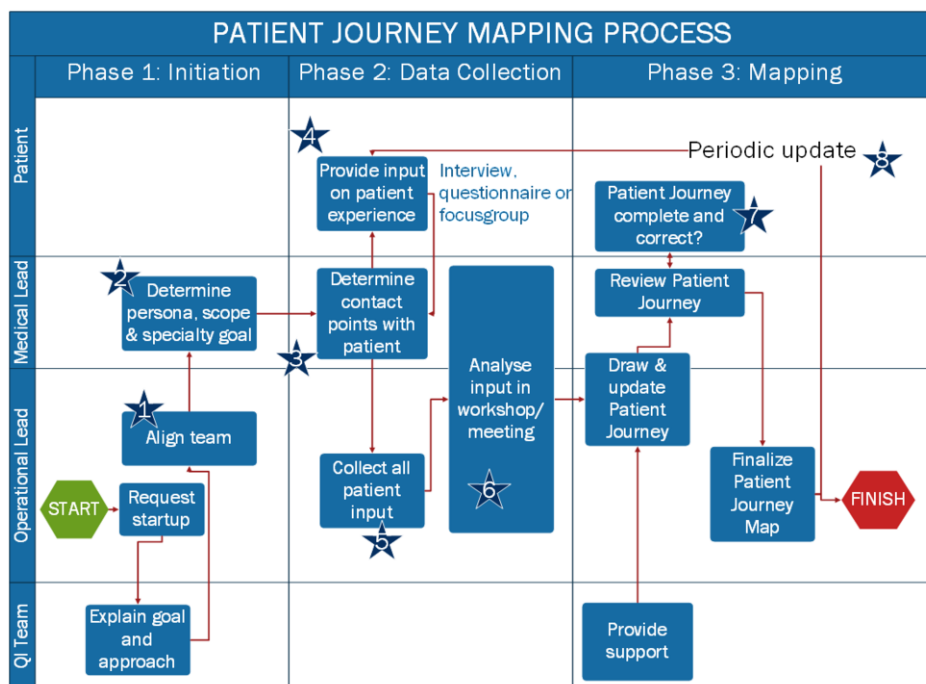

Figure 1. Swimlane diagram showing Lean improvements for patient journey mapping. Stars indicate improvement suggestions, QI Team = Quality Improvement Team

The numbered stars highlight the accepted Lean optimizations. Below each optimization is described in detail.

- *Star 1- Align team upfront*
Prevent wasting time and effort on discussion and confusion about who is supposed to be involved in which actions by agreeing up front on the roles and responsibilities between QI Team, Medical Lead and Operational Lead.
- *Star 2 – Faster determination of persona, scope and goals*
Reduce time and effort spent by healthcare professionals on determination of persona, scope and goals by providing guidance on how to do this.
- *Star 3 – Use available resources to determine contact points with patient*
Prevent having to change the patient journey later on by using available system data to determine contact points with patients.
- *Star 4 – Collect high quality input on patient experience*
Increase quality of data on patient experience by providing guidance on the selection of patients and by standardizing questionnaires for collecting data about patient experience.
- *Star 5 - Only start a workshop when all input is available*
Make sure all required data which is needed in a workshop is available, so that the workshop can deliver expected outputs without wasting time and energy of attendees.
- *Star 6 - Reduce amount of workshops*
Do not organize workshops if the goal can be realized by using other means of communication so that timelines are reduced.
- *Star 7 - Review patient journey map with patient*
Increase quality of the patient journey map by reviewing the map by a patient (or representative) before finalizing it. This prevents rework later on and prevents healthcare professionals from spending time on analysing incorrect or incomplete patient journeys.
- *Star 8 - Periodic update*
In a changing world a patient journey map needs regular updates to stay up to date. Otherwise time is waste on analyzing incomplete or incorrect patient journeys and opportunities to improve patient experiences are missed out.

Rejected improvements included: the creation of online instruction materials to reduce time needed to attend a workshop, the creation of online instruction materials, to replace focus groups and questionnaires for collecting patient input by phone calls and drawing the patient journey map once instead of twice (during workshop on paper/ board and after workshop in electronic format).

4. Discussion

In this study we assessed the value of Lean for improving the patient journey mapping process in an academic hospital setting. First, the Swimlane diagram helped with aligning different views on the current mapping process and with structuring the process activities. Secondly, an expert panel reviewed eight out of 11 Lean suggestions based upon Lean waste analysis as valuable and fitting their hospital vision on patient journey mapping.

Other studies also confirmed the value of Lean for optimizing and standardizing processes in healthcare settings, resulting in quality improvement. The systematic review performed by Glasgow in 2010 showed ample examples of successful quality improvement initiatives based on Lean, varying from improving laboratory tests to radiology processes [9]. A strength of our study is to base the Lean analysis upon observation of an actual patient mapping process from initiation till finalization by an independent researcher. Other strength include the execution of the Lean analysis by a Lean expert and the involvement of an expert panel in reviewing the Lean improvements.

A limitation of the setting of this study is that all healthcare professionals involved were mostly unexperienced with patient journey mapping which is reflected in the process. For example there is a higher need for clear instructions and examples, teams had to get aligned at the startup of a new patient journey process execution, etc. The improvement findings might therefore differ from a setting where an experienced team is executing the process.

On the basis of this work, we conclude that Lean can provide value for aligning different views on the process, for structuring the process activities and phases and for identifying optimization actions in a patient journey mapping process. The mapping process described by us is a first step in optimizing the process for patient journey mapping. Further validation and adjustments are needed to come to an optimal process. We look forward to further develop the process for patient journey mapping and intend to validate the proposed model in the near future.

Abstract. User experience (UX) theories, models, and frameworks (TMFs) help scope user-centered design activities, aid in the selection of constructs and measures, and contextualize findings within a larger knowledge base. However, the fragmentation of literature across disciplines and the inconsistent use of TMFs makes integrating concepts and selecting UX tools challenging. Therefore, we conducted a focused review of the healthcare literature to identify a succinct list of UX-specific TMFs for academic UX researchers and industry practitioners alike.

Keywords and MeSH terms. Human-Computer Interface, Theoretical Models, Ergonomics, human factors, usability, frameworks, user experience.

1. Introduction and Problem Statement

User experience (UX) encompasses user perceptions and responses resulting from the use or the anticipated use of a product, system, or service [1]. Because UX research in healthcare is a high-stakes endeavor, questions arise concerning methods and instrumentation. For example, “what methods best suit the context?” and “how will we know if a technology is effective?” Practitioners can use theories, models, and frameworks (TMFs) to answer these questions. Using Nielsen’s definitions, we define “theory” as a set of statements that explain observable phenomena, “model” as a descriptive simplification of those phenomena, and framework as the lexicon to organize constructs [2].

Collectively, TMFs scaffold UX work by organizing concepts, aiding in method selection, and contextualizing results [3]. Because it can be challenging to stay abreast of the literature, we offer a focused review of relevant TMFs reported in healthcare. Our goals were to (1) provide a succinct list of UX TMFs used to study health information technology (HIT); (2) describe several general models that can meet a wide array of UX research needs; and (3) identify theory-research and theory-practice gaps and opportunities.

2. Methods

We completed a PubMed search from 1946 through to 2019 using the following medical subject headings (MeSH) terms and keywords: “Human-Computer Interface

¹ Lesselroth, Blake, E-mail: Blake-Lesselroth@ouhsc.edu.

OR Ergonomics OR human factors OR usability OR technology acceptance OR user experience” AND “Models, Theoretical OR Models, Psychological OR Information Theory or Systems Theory OR frameworks”. We restricted the results to manuscripts applying a theory, model, or framework to healthcare and limited output to “human subjects” and “English language”. We excluded articles of methods without TMFs.

3. Results

We identified 4369 article titles, selected 307 for abstract review based upon relevance (i.e., if they described technology development or implementation), and 104 for full text review. We identified 101 unique articles speaking to UX and related disciplines including implementation science, software development, and cognitive psychology². Of those articles retrieved, 36 TMFs expressly addressed user experience, interface design, or interface usability.

4. Discussion

Principle Findings and Three Key Models

We identified 36 unique TMFs describing UX studies of HIT. Many articles used TMFs from related fields or pragmatically borrowed constructs without articulating a link to UX theory. We purposefully selected three examples of UX models for further discussion: the User Centered Design Development Lifecycle, the Cognitive Socio-technical Framework, and the Task, Users, Representations, and Functions framework [3-5]. These are “general purpose” models (i.e., provide a range of constructs and explanatory interactions) developed expressly to facilitate UX work at any stage of development. Other models may be better tailored to a particular task or context such as app development or designing for the elderly.

The User Centered Design Development Lifecycle, described by Nielsen, is a cycle of activities fusing iterative design-thinking with the software development lifecycle [6-8]. Yen adapted this model to healthcare by tracing development stages to evaluation methods and healthcare goals [3]. The model describes three phases. The pre-design phase calls for UX instrument preparation during project planning. The design phase includes four steps: (1) specifying user needs; (2) defining requirements; (3) designing components and; (4) combining components. The post-design phase includes two steps: (1) system integration; and (2) routine use (i.e., UX to optimize regular use) [4, 5, 7].

Borycki and Kushniruk’s Cognitive Socio-technical Framework (CSF) integrates two complementary characterizations of user interactions: (1) cognitive models describing how humans process information and; (2) sociotechnical models describing how technology affects work [4]. The framework suggests UX evaluation methods throughout the technology lifecycle. Initially, researchers should study the interaction between technology and individual. Later, researchers can examine work processes among groups in context.

The Task, Users, Representations, and Functions (TURF) framework developed by Jiajie Zhang is a four-step sociotechnical model that emphasizes the interactions between users, tasks, and functions [5]. The first step requires identification of all system users. In the second step, researchers gain an understanding of the work by developing an ontology of activities, interactions, and knowledge. Then, teams can look at software through multiple lenses to identify unmet needs. The third step is a

task analysis wherein researchers catalog tasks associated with complex activities to measure complexity and time on task. Finally, the team can study how effectively data displays represent concepts.

Limitations and Opportunities for Future Research

We only searched PubMed using MeSH terms and keywords; we did not search other bibliographic databases. A future systematic review should include other bibliographic databases (e.g., Scopus, Embase), trade publications, and grey literature.

Future research needs to focus on: (1) schematizing the dimensions of usability; (2) predicting the effect of constructs upon outcomes; and (3) publishing practical guides linking TMFs to use-cases, technology phases, and study methods [9, 10].

5. Conclusions

Application of UX TMFs can help scope projects, address usability issues, and improve overall system performance. However, the state of the literature makes it difficult to integrate concepts and apply to practical problems. Although we provided a list of generalizable models, we have identified opportunities to close the theory-practice gap.

Abstract. A well-designed social platform has the potential to reduce senior isolation and promote active ageing. However, to design tools that respond to the user need it is important to understand what types of seniors will use it and what are their needs. Through a user-oriented approach at several design stage: focus group, co-creation and usability test we were able to identify the different roles related to the use of the platform, which allowed us to classify them by type, each type having very specific needs. Among the types of users identified, “Active users” are looking for an efficient platform. “Socialiser users” are more passive and mainly interested to participate in activities and are sensitive to trust. “Low skilled users” have limited digital skills and must be accompanied to start with the platform. Finally, “Sporadic users” lack of time to actively use the platform but would use a platform involving a large number of stakeholders. It is important to include all these different types of users in the design phase to ensure the future success of the social platform.

Keywords. Aged, social participation, social media, needs assessment, user-computer interface

1. Introduction

While good quality of life among seniors is correlated with an active social life [1], loneliness is strongly associated with depression, thus decreasing well-being of elderly [2]. Unfortunately, prevalence of loneliness in Europe is still high since it has been measured at 9.6% in older adults [3]. One way to fight isolation is to strengthen the social link between communities. Researches showed that participation in social activities can be motivated by online social support platforms [4,5]. While some researches have studied seniors' requirements to use social media [6-9], only few studies have focused on the different type of seniors' users and their heterogeneous needs. *PaletteV2* is a

¹Corresponding author: E-mail: Arnaud.Ricci@hcuge.ch

European project aiming to develop *Palette*, an online social support platform for seniors to encourage them to an active and social life. The aim is to provide to seniors a user-friendly online platform that gives them access to likeminded people and activities, aligned with their interests. They can create different types of events such as recreational or volunteer events and search for their activities according to their interests and by type of event. They can also easily discuss with the creator of the activities.

It is known that ageing influences how people feel comfortable using technologies and how they learn to use new technologies [10]. To ensure the success of any product and its adoption by users, it is essential to understand end-users needs and to design and evaluate it with a range of potential end-users at each stage [11]. An iterative user-centered design process took place in which the interface was iteratively ideated, designed and evaluated with end-users at each stage of the project. In this article, our goal is to present the different users types of such platform and their requirements.

2. Methods

The development of the social platform named “*Palette*” was conducted as an iterative process involving targeted users at each stage. First, focus-groups allowed us to identify user’s difficulties and needs [12]. This stage highlighted their desire of seniors to engage in meaningful and social activities. Then, co-creation sessions were organized to understand how an online platform could support this goal and to ideate the platform functionalities with end-users [9]. Finally, prototypes and final platform were iteratively tested with end-users to assess and improve the usability [13].

During this whole process we collected a large amount of information about our user group and aimed to classify them into categories regarding their intended and actual use of the platform. Then we associated these categories with their main need and barrier regarding the platform

Although there is no strong consensus on a single taxonomy, there are several attempts to classify social network users in particular categories depending on their behavior. To classify our users, we were guided by the research of Brandtzaeg & Heim (2011) [14], which define five roles of users on social networks: sporadics (new comers and users who use the platform irregularly), lurkers (people using media for lurking or time-killing), socialiser (early majority, intermittent contributors), debaters (early adopters, intermittent contributors), active (users who actively participate on social networks).

3. Results

3.1. *Participants*

In total, 165 end-users participated in the participatory design process of the platform. Focus groups were held in 3 countries, Switzerland, the Netherlands and Romania from August to December 2016. The first session was organized in the Netherlands and Switzerland and included 4 participants each time (average age = 75 years) and the focus groups that followed included 2-3 sessions each with 4-6 participants aged 50 to 80 years (average age = 64 years). This represents a total of 41 participants. Co-creations sessions took place in March 2017 in the same countries with a total of 47 participants (mean age = 67 years). Concerning usability testing of the platform, it involved 5-10 participants

ages between 50-80 years old (mean age = 68 years) in each country with a total of 77 participants.

3.2. Types of users and their requirements

During the different design phases, we were able to classify our participants into 4 categories guided by the Brandtzaeg & Heim model (2011). However, we had to create a new category to consider users who do not have the necessary skills to use the platform despite their willingness to use it.

Some participants did not have the necessary skills to get involved, others wanted to get involved minimally, others wanted to be actively involved and finally participants did not have the time to get involved. Based on these 4 types of users we associated their need and barrier from the data collected at the different design stages,

Table 1. Type of users, needs and barriers

<i>Type of user</i>	<i>Needs</i>	<i>Barrier</i>
<i>Low skilled user</i>	<i>Improving digital skills</i>	<i>Independence</i>
<i>Socialiser user</i>	<i>Platform offering a wide range of activities and a wide variety of offers</i>	<i>Trust</i>
<i>Active user</i>	<i>Easy-to-use platform with feedback and quickly and easily publish and evaluate events</i>	<i>Poor platform ergonomics</i>
<i>Sporadic user</i>	<i>Have all the activities organized in the municipality</i>	<i>not a lot of time (socially active) and very busy</i>

Low skilled user - seniors with poor digital skills

Due to their poor digital skills, some of these seniors do not have an email address. They also have difficulty using a keyboard or a mouse. People with such profile needs to be helped in order to use the platform. This category of seniors considers that the use of the platform could be a good way to improve their digital skills. To use the platform by their own, they would need a support functionality. Organizing meetings to teach them the basics of computer use in addition to test the platform could be beneficial to them and could allow this category to benefit from this service. This is a category that is not found in the Brandtzaeg & Heim (2011) model because their model does not take into account people who do not have enough skills to use social networks but would like to use them.

Socialiser user - seniors who just want to participate in activities

This category can be considered as poorly qualified regarding their digital skills. They sometimes have doubts about Internet security. Some of them don't feel safe trying things on the Internet and they are afraid of making mistakes. They are interested in the concept of the platform and want to use it to meet people and find activities but they don't want to organize events themselves. For these seniors, it's necessary to offer a platform offering a wide range of activities and a wide variety of offers, including support services. They would like to have a system that shows all the offers grouped by municipality or region. This category of users' needs to know that the platform is

trustworthy. One way to do this is to use a moderator to moderate the content. Ideally, it should be a local person who can be contacted by phone or email.

Active user - seniors who are active and want to offer events

This profile of seniors is active and wants to help others, invite others to join activities in which they have already participated or to propose activities they organize themselves. They are often more comfortable with digital than the others. They are often effective in explaining to other seniors how the platform works. The platform must be easy to use with system feedbacks. For example, that tells them that they have correctly created their events and to make sure that other users have access to them. For people who offer several activities it's important to quickly and easily publish and evaluate events. In particular, it should be possible to create an event without a specific start and end date.

Sporadic user - seniors who are socially active and too busy

This category of senior are very socially active with a busy schedule, they don't feel the need to use such platform. They don't really have something to offer and they don't need to use it to have social contacts and participate in activities. Although this category of seniors is not the most concerned by the platform, it can be useful for them to have a platform where all activities of municipalities and organizations are centralized and displayed. The platform could be used by some as an online agenda and replace the activities posted on the different websites.

4. Discussion

Seniors attitudes' and uses' of digital tools is known to be heterogeneous [15]. The user-centered approach used throughout the project allowed us to identify four types of users to consider when creating an online social platform for seniors. Each type have specific needs and thus a different use of an online social platform.

Among the types of users identified, the "*Active users*" want to participate actively to the platform by providing a lot of activities. For them, the most important is to have an efficient platform to avoid losing time in using the platform. To satisfy this need, it is important to be able to filter by categories the different events proposed. It is also important to be able to sort according to the user's interests, otherwise the platform becomes complicated to use when it offers many events. "*Socialiser users*" are more passive and mainly interested to participate in activities. They are looking for various content and are sensitive to the trust in the platform. To address trust issue, a moderator role is important to moderate the content and strengthen users' trust in the platform. "*Low skilled users*" have limited digital skills, highlighting the importance of offline training sessions to help to get started with the platform. It is also necessary to ensure that the various functionalities are easy to access and use. Online tutorials should also be offered to these users. Finally, "*Sporadic users*" are already socially active and lack of time to actively use the platform, they would still use it as an event reference if the municipality's activities were listed on it. This requires involving stakeholders like municipalities as event provider in platform if we want to attract this type of senior.

When developing such platform, it is important to include all types of end-users into a user-centered process to make sure the tool meet the needs of all users.

Abstract. The paper introduces a structured approach to transforming healthcare towards personalized, preventive, predictive, participative precision (P5) medicine and the related organizational, methodological and technological requirements. Thereby, the deployment of autonomous systems and artificial intelligence is inevitably. The paper discusses opportunities and challenges of those technologies from a humanistic and ethical perspective. It shortly introduces the essential concepts and principles, and critically discusses some relevant projects. Finally, it offers ways for correctly representing, specifying, implementing and deploying autonomous and intelligent systems under an ethical perspective.

Keywords. pHealth, P5 medicine, autonomous systems, artificial intelligence, ethical principles

1. Introduction

In many countries, specific initiatives and strategic programs are established and continuously updated, aiming at improving care quality, patient safety, and care process efficiency and efficacy, thereby moving from volume to value based care to respond to the challenges health systems face. Those challenges are, e.g., ongoing demographic changes towards aging, multi-diseased societies, the related development of human resources, a health and social services consumerism, medical and biomedical progress, and exploding costs for health-related R&D as well as health services delivery. Organizational, but especially by disruptive methodological and technological paradigm changes enable this move. The paper shortly introduces in those paradigm changes and the accompanying organizational and ethical challenges and proposes

¹ Corresponding Author. Bernd Blobel, PhD, FAACMI, FACHI, FHL7, FEFMI, FIAHSI, Professor, University of Regensburg, Medical Faculty; Regensburg, Germany; Email: bernd.blobel@klinik.uni-regensburg.de

principles and methodologies for mitigating them, thereby critically discussing some ongoing solutions and projects.

2. Methodological, Technological and Organizational Paradigm Changes

Methodologically, phenomenological and evidence-based medicine, both relying on population-based diagnostic models based on retrospective data sets, slowly evolve towards personalized, preventive, predictive and participative precision (5P) medicine. It considers individual health state, conditions and social, environmental, occupational and further contexts at bedside in relation to the community, fully understanding the specific pathology of the health problem [1]. This requires the multidisciplinary approach of systems medicine, deploying the explicit and enhanced knowledge of all stakeholders from the different domains to be involved including the subject of care in the center, replacing the observational and analytical medicine approach [1]. Christensen et al. described healthcare transformation as move from intuitive through empirical to precision medicine [2]. Involved disciplines/domains include medicine and public health, natural sciences, engineering, administration, but also social and legal sciences and the entire systems sciences world (systems medicine, systems biology, systems pathology, etc.). Organizationally, health systems transform from an organization-centric through a cross-organizational, pre-defined and process-controlled to a context-sensitive, individually tailored, highly dynamic, fully distributed personalized care paradigm. The latter is sometimes also called ubiquitous care or care anywhere at any time. With a stronger focus on the information and communication technology (ICT) support, thereby referring to pervasive computing technology, another term frequently used is pervasive care. Both described paradigm changes are supported, impacted or even enabled by related technological paradigm changes. Here have to be mentioned: Mobile, nano-, bio- and molecular technologies; artificial intelligence (AI); robotics; bioinformatics; big data and prescriptive (based on current data) as well as predictive (includes future outcome) analytics; natural language processing (NLP) and understanding (NLU); cloud computing; cognitive computing and social business; but also the Internet of Things (IoT) [3]. A more detailed description of health systems transformation is provided in [1].

We cannot place health and care specialists, educators, lawyers, etc., next to every person to be comprehensively served. Ubiquitous 5P medicine requires the deployment of robotics and artificial intelligence, or more generally autonomous and intelligent systems (AIS), aiming at [3, 4, 5, 6]:

- a) capability and engagement augmentation for care provider and subject of care including education, access to information and services, thereby advancing accuracy, precision, location independency [7];
- b) enabling cooperation;
- c) improved staff and patient experience;
- d) process improvement including clinical workflow and scheduling, but also business efficiency, productivity and cost containment as well as risk analysis;
- e) facilitating faster and more precise decision at administration, direct and indirect caregiver, and patient level including prognosis;
- f) collaborative business intelligence as self-service.

More details on types of artificial intelligence, services and related challenges especially in the health and social care context are provided, e.g., in [8].

Any action and relationship in enlightened democratic societies, but especially the health, care and welfare system have to accommodate legal, moral and ethical principles. In the next chapters, we will consider the different levels of AIS, reference moral and ethical principles, discuss initiatives and projects tackling the ethical challenges, and finally propose a sound approach for addressing this problem.

3. The Ethical Challenge of AIS

Social contracts and law define and enforce behavior for maintaining social order, peace, and justice in society. Ethics provides code and conduct guiding to decide what is good or wrong, and how to act and behave properly, thereby establishing as well as defending rules of morality and frequently going beyond the law [9]. With the evolution of societies including sciences and technologies, different approaches to, or theories on, ethics have been developed in the framework of meta-ethics, normative ethics and applied ethics. Here, Aristotle’s and Plato’s virtue ethics, Kant’s deontological ethics, Mill’s utilitarian ethics, and Rawls’ justice as fairness ethics have to be mentioned [9]. Ethical values are strongly impacted by culture, social norms and geographic locations. Having the evolutionary characteristics of ethics and the terrific social and technological developments in mind, there is no chance for one global comprehensive standard of ethics. Instead, basic social ethical principles such as dignity, freedom, autonomy, privacy equality and solidarity, or the more technological categories like fairness, robustness, explainability, and lineage have been established. For bridging the gaps (at least partially), trust through transparency is discussed as solution [10]. Societal and policy guidelines help to remain human-centric by supporting humanity’s values and those ethical principles [11]. There are many organizations and initiatives proposing ethical frameworks and design methodologies for AIS, such as the EU Council of Europe with its “Guidelines on Artificial Intelligence and Data Protection”, the Future of Life Institute with the “Asilomar AI Principles”, IEEE with “The IEEE Global Initiative on Autonomous Systems”, the U.S. Congress Resolution “Supporting the Development of Guidelines for the Ethical Development of Artificial Intelligence”, the OECD “Principles for AI Research and Development” proposed by the Conference Toward AI Network Society, April 2015, in Japan, The World Economic Forum “Top Ethical Issues in Artificial Intelligence”, and many others. An overview about those initiatives, some content details and references are provided in [8]. Table 1 summarizes the common principles of some of them.

Table 1. Common ethical principles proposed by different organizations

Guideline Originator	Transparency	Accountability	Controllability	Security	Value Orientation Ethics	Privacy	Safety	Risk	User Assistance
OECD	x	x	x	x	x	x	x		x
IEEE	x	x	x		x	x		x	x
Asilomar	x	x	x	x	x	x	x	x	
US Congress	x	x	x	x		x	x		x
World Economic Forum				x	x			x	

4. Representing/Modeling Ethical, Moral and Legal Concepts

Ethics and morality are complex humanistic domains with social, legal, religious and philosophical impact. Their concepts, relations and constraints on them can be represented but not be defined and justified in ICT viewpoints due to the context-free, highly expressive and formal languages deployed, resulting in inconsistent, indefinite and incomplete models. Instead, the concepts, relations and constraints of the domains contributing to the real-world business system must be formally represented and interrelated/harmonized using the ISO 23903 Interoperability and Integration Reference Architecture approach [12]. Its system-oriented, ontology-driven, policy-controlled formal representation of real-world business systems and the related software development process extends ISO/IEC 10746 Open Distributed Processing – Reference Model and turns it into a multi-domain model [13]. Figure 1a presents the AIS use case to be automatically transformed into corresponding ICT solutions.

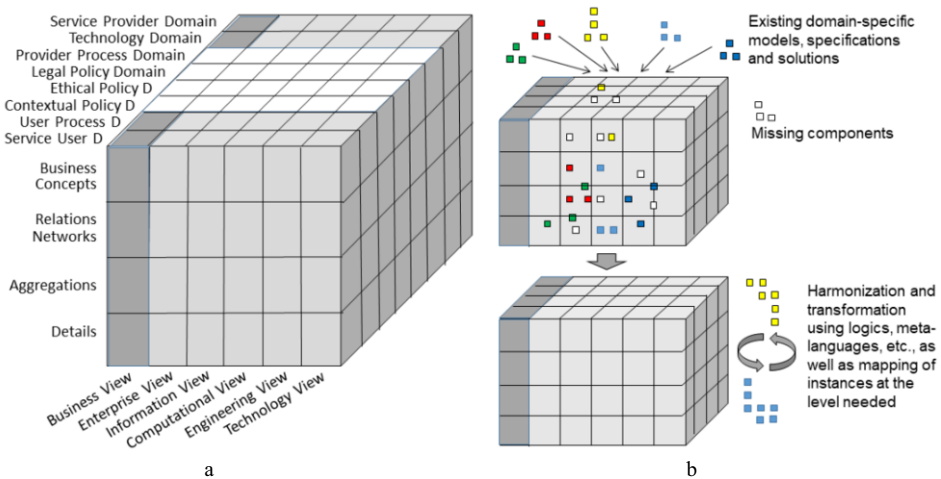

Figure 1. AIS representation, design and implementation enabling advanced interoperability and integration acc. to ISO 23903

Despite the aforementioned limitations regarding the ICT modeling of complex systems, overcome by profiling specifications and remaining at quite generic level, projects have been established to specify implementable components representing ethical and context-related behavior. Here, efforts in modelling morality with prospective logic [14], but also the IEEE P70xx project series [15] have to be named. As they just focus on the ICT representation, they must be integrated and correctly interrelated using the ISO 23903 framework as shown in Figure 1b.

5. Discussion and Conclusions

It is crucial to define objectives, constraints and limits for AIS as well as inevitable principles and not acceptable behavior, auditing their entire lifecycle. In that context, AIS can never be used as means relinquishing or displacing humans' responsibility [10]. The complexity of AIS and the multiplicity of interaction levels for ethical behavior require the consideration of all aspects of human value instead of defining and

implementing a sub-set of legal and ethical principles. Modelling such AIS and their components must be performed following Good Modelling Practices [16, 17], starting with the multi-disciplinary knowledge space, its formalization and harmonization. Many of the ongoing ethics-related projects are limited to ICT perspectives, ontologies [18], and representation styles. The IEEE P7007 project "Ontological Standard for Ethically Driven Robotics and Automation Systems" for example starts with representing some ethical principles and scenarios as UML diagrams, whose elements are then axiomatized using the free and IEEE owned Suggested Upper Merged Ontology (SUMO), developed as foundation ontology for a variety of computer information processing systems. For integration with other specifications, the deployment of the ethical domain ontology represented in the domain's language [19] is inevitable. The current ISO 23903 project provides an appropriate framework also for developing ICT solutions under legal and ethical concerns. A recent formulation of those concerns is provided in [20].

Big Data, Information Technology and Information Professionals: Some Considerations for Digital Ethics

E-H. KLUGE,¹

^aIMIA (SiHIS) and University of Victoria

Abstract. It is generally accepted that the global evolution of health information technology, both in design and usage, raises ethical issues that should be addressed. However, the terms in which this concern is expressed are shrouded in ambiguity. Even what constitutes an ethical issue itself is never clearly defined. The present discussion attempts to clarify the landscape and suggests how the concern should be addressed.

Keywords. Information technology, digital ethics, certification

1. Introduction

It is generally accepted that the global evolution of health information technology, both in design and usage, raises ethical issues which should be addressed. Big Data, digital ethics and information technology, as well as the behavior of health informatics professionals and institutions stand at the center of concern. However, as so often happens, the problematic itself as it is usually stated is essentially unclear. For example, what counts as Big Data? What is covered by the phrase “Information Technology?” Who is an information professional? What is meant by “Digital Ethics?” More importantly still, why would anyone think that ethical considerations are worth looking at in this connection? Why not let pragmatic and legal considerations carry the day?

2. Some Clarification

Perhaps the best way to answer these questions is to start with the phrase “Digital Ethics.” It is of course a phrase of art. It refers to the ethical parameters that play a role in the design and use of digital technology. It assumes that there are special ethical considerations that are relevant whenever digital technology is designed or used in informatic contexts in health care.

Like all assumptions, this assumption should be justified. However, doing that assumes that the phrase “ethics” itself is clear and unambiguous—and unfortunately, that is not the case. What people call ethics often has nothing to do with ethics but instead refers to custom, ethos and even to law. Ethics deals with the moral

¹ Corresponding author, University of Victoria, Finnerty Road, Victoria, BC, Canada; E-mail: ekluge@uvic.ca

principles that govern a person's behavior or conduct. This immediately distinguishes ethics from law. While legal considerations may overlap with ethical considerations, and while one may hope that laws, legal traditions, protocols or codes of conduct are grounded in ethical principles, this is not necessarily the case. The reason is that laws, protocols and codes of conduct are rules that are created by a duly constituted authority to regulate the behavior of members of society or of associations. They may be grounded in ethical principles, but that is not necessarily the case. Ultimately they are dependent on the decisions of those who promulgate them. Ethical principles are not thus decision-dependent. They are grounded in what it is to be a person. Therefore they hold irrespective of whether they are recognized in law, tradition or ethos, and independently of whether they are enshrined in legal stipulations, quasi-legal codes or protocols.

There have been various attempts to show how these principles should be reflected in ethical guidelines or codes of practice by providing lists of so-called fundamental values such as privacy [1], justice [2], autonomy [3] etc. There have even been attempts to systematize and collect these values into a matrix applicable to information technology in general and Big Data in particular [4]. However, values are what people consider important. Therefore, they are ultimately psychological in nature. Hence they may differ from individual to individual and from society to society. To have truly objective validity, ethical guidelines and codes should ultimately be grounded in the principles that are enshrined in Universal Declaration of Human Rights.

When these latter principles are particularized to the informatic context, they emerge as Principles of Information Ethics [5]: the Principle of Privacy and Disposition (All persons and group of persons have a fundamental right to privacy, and hence to control over the collection, storage, access, use, communication, manipulation, linkage and disposition of data about themselves.); the Principle of Openness (The collection, storage, access, use, communication, manipulation, linkage and disposition of personal data must be disclosed in an appropriate and timely fashion to the subject or subjects of those data.); the Principle of Security (Data that have been legitimately collected about a person should be protected by all reasonable and appropriate measures against loss, degradation, unauthorized destruction, access, use, manipulation, linkage, modification or communication.); the Principle of Access (The subjects of health records have the right of access to those records and the right to correct them with respect to their accurateness, completeness and relevance.); the Principle of Legitimate Infringement (The fundamental right of privacy and of control over the collection, storage, access, use, manipulation, linkage, communication and disposition of personal data is conditioned only by the legitimate, appropriate and relevant data-needs of a free, responsible and democratic society, and by the equal and competing rights of others.); the Principle of the Least Intrusive Alternative (Any infringement of the privacy rights of individuals, and of their right of control over these data, may only occur in the least intrusive fashion and with a minimum of interference with the rights of the affected parties.); and the Principle of Accountability (Any infringement of the privacy rights of a person, and of the right to control over data about them, must be justified to the latter in good time and in an appropriate fashion.). These Principles govern—more correctly, perhaps, should govern—the development and use of any information technology and the conduct of those involved with it in a professional or institutional capacity.

3. Digital Ethics, Big Data and Electronic Health Records (EHRs)

Which brings the discussion to digital ethics, Big Data and electronic health records (EHRs). Digital ethics is merely information ethics applied to digital data, and Big Data is nothing more than the collection and manipulation of vast amounts of data.

Here it is important to remember something that is often ignored. Technology itself is ethically neutral. It is just that: technology. It is its use that has ethical implications. When it is used in an ethical manner this not only serves a useful purpose but also advances otherwise legitimate aims. For instance, the scientifically valid and ethically appropriate collection, storage, use and manipulation of data can advance the delivery and effectiveness of health care. Likewise, without this modern medical research would essentially be impossible. What is ethically indefensible is collecting and using data sets inappropriately, surreptitiously or without consent—as was done by Cambridge Analytica.

As to why digital ethics takes a special turn in health informatic contexts, the reason lies in the nature of EHRs. Viewed materially, they are merely electronic entities with certain characteristics; viewed informatically, they are the totality of data that have been generated about a given patient: As such, they are patient analogues in data-space; and because of their relationship to their subjects, they are subject to ethical considerations [6].

And this also has practical implications. Because if it had no practical implications, then digital ethics would be a nice conceptual exercise—the sort of thing one would consider in a theoretical university seminar—but it would be pointless to worry about it in real life.

Legal and policy requirements of course also have practical implications. However, they are only as good as their last version, and as the example of the GDPR shows [7] they may be altered over time; and as changes in informatic laws of various countries show, these may even overturned [8-12]. Therefore institutions and professionals who only follow legal or quasi-legal provisions may find themselves in an uncomfortable position when these are changed or amended. And there is also the fact that statutes and similar provisions are meaningless in practical terms until they are interpreted. To be sure, they set relevant frameworks, but what they mean in real terms is a function of how they are interpreted in actual cases. Therefore, as the old saying goes, “To rely on law is to be only as safe as the last case that interpreted the relevant statute.”

This, then, is where ethics is different and where ethics “bakes bread.” An institution that follows the fundamental principles of information ethics in its protocols and provisions will reap three practically important advantages: (1) It will not have to make fundamental changes in its protocols and operational guidelines as time progresses and statutes or quasi-legal provisions change. (2) It will be able to use its protocols in inter-jurisdictional settings because they are not law-based but ethics-based. (3) They may hold themselves out as providing ethically impeccable services—which can be advertised to tremendous commercial advantage. Therefore, again, “Good ethics is good business.” As for professionals, ethically sophisticated professionals make good employees; and it is very difficult to accuse someone—or to find them guilty—of inappropriate conduct when they have acted in an ethically appropriate manner.

4. Conclusion

However, having an ethically valid framework for digital ethics and supplying informatics professionals, institutions and other users with ethical protocols and guidelines is one thing; ensuring that the stipulations that govern the framework are understood and that the guidelines are actually followed is another. That can be achieved only by putting in place an independent and objective body that provides such guidelines and that monitors how all of they functions in actual practice. There currently is no such body. Therefore ethics-in-application essentially remains a haphazard and spotty affair.

However, even if such a body existed, that would only be part of that story. What also is missing is some means of ensuring that professionals and institutions are qualified to follow ethical guidelines and protocols in the first place, and are actually able to operationalize ethically its tenets when using the digital technology as it currently exists or as it changes with the advent new technology and with changes in the structure of health care deliver itself.

Fortunately, some of these considerations have already struck a responsive chord at the global level. The need of providing an overall ethics framework was addressed by the International Medical Informatics Association (IMIA) when it promulgated its Code of Ethics [13], latter which constitutes the overarching framework of the ethics codes of its member associations. As for the need to ensure that professionals and institutions are actually qualified to operationalize this ethical framework, this is what underlies the ethics-certification project that is currently being worked on by a subgroup of IMIA. It is expected that this work will have the endorsement of WHO and associated agencies. Clearly, if and when this it comes to fruition it will have practical implications for Big Data, information technology, information professionals and digital ethics on a global scale. However, whether it comes to fruition only time will tell.

Abstract. Understanding motivation and resistance factors affecting citizen participation in health and scientific research allows to find solutions to improve citizen engagement and interest in science. Through a survey, we identified the main factors influencing citizens' participation in scientific research, and their wishes to be more informed. Results show that the respondents' reasons to participate in research were altruistic motivations, in line with other studies carried out in developed countries. The main factor influencing the non-participation is the lack of opportunity, highlighting the importance to better inform citizens about ongoing studies.

Keywords. Community participation, motivation, attitude, research, clinical trial, ethics, global health

1. Introduction

Reasons why citizens participate or not in scientific research have been studied in the fields of sociology and psychology. While research has been conducted on motivational engagement in research in Europe [1-3], Brazil [4] and USA [5], no studies have yet investigated the context of Switzerland.

Switzerland is a country with a specific legal context. As not being part of the European Union, it does not have to comply with the same legal framework. However, following the General Data Protection Regulation (GDPR) in Europe [6], a Swiss Federal Act on Data Protection has been created. The relation of the Swiss citizens to their personal data might be country specific and it may have an impact on their willingness to participate in scientific studies.

In this paper, we describe a survey that was developed to understand the motivation and resistance factors affecting citizen participation in health and scientific research but also their wish to be more informed. It aims at understanding the processes behind these decisions and to gain an insight on how to improve this situation.

¹ Corresponding author: Faculty of Medicine, University of Geneva, Switzerland; E-mail: jessica.rochat@hcuge.ch

2. Methods

We developed a survey with questions related to motivational and resistance factors that may affect citizen participation in health and scientific research. Questions and multiple-choice answers were derived from a literature review to identify factors that motivate or dissuade people to participate in scientific studies and clinical trials. The survey was distributed in French to citizens during two general public events held between July and November 2018 in Geneva (Switzerland), aimed at raising citizens' awareness about science.

The survey was separated into three parts: 1) What are their motivations to participate in scientific studies (e.g. surveys, psychology's experiments) and/or clinical trials? These questions were multiple choices with several possible answers. 2) Why did they never participate in scientific studies and/or clinical trials? These questions were also multiple choices with several possible answers. 3) What do they want to be informed about?

Concerning parts 1 and 2, since several answers were possible, the number of responses to each question was divided by the total number of responses to all the proposed answers. This allowed us to compare response frequencies out of a total of 100%.

3. Results

A total of 124 participants completed the survey. 52% were women (n=64), 46% were men (n=57) and 2% (n=3) did not answer to this question. The mean age was 43 years old. The majority of participants were Swiss (66%) and French (18%). Concerning the level of education, 1% of respondents (n=1) did compulsory school, 11% (n=14) went to high school, 72% (n=89) have a higher or university level, and 16% (n=20) did not answer.

58% (n=72) of participants reported they had already participated in a scientific study (e.g. questionnaires, psychology's experiment) while the remaining 42% (n=52) had never participated in a similar study. Among the participants who already participated in a scientific study, 60% (n=43) had participated in questionnaires, 63% (n=45) in an experiment and 19% (n=14) in another type of survey (e.g. interviews). Concerning clinical trials, 9% (n=11) of the respondents stated they had participated in a clinical trial.

3.1. *Motivations to participate in scientific studies and clinical trials*

Scientific studies

They were 72 responders to the question about the motivations to participate in scientific studies. Figure 1 shows that the motivational factors most often chosen were "to help the science" (30%), followed by "to help the organizer of the study" (25%) and "to help people concerned by purpose of the study" (21%). "Financial compensation" represented only 11% of the responses, followed by "to help relatives concerned by the purpose of the study" (5%), "I'm directly concerned by the purpose of the study" (4%) and others (4%).

Clinical trials

They were 11 responders and figure 1 shows that the main motivational factors concerning the participation in clinical trials were “to help the science” (28%), followed by “to help people concerned by the purpose of the study” (24%) and “to help the organizer of the study” (24%). “Financial compensation” and “I’m directly concerned by the purpose of the study” represented only 10% of the responses, followed by “to help relatives concerned by the purpose of the study” (4%).

Figure 1. Distribution of motivations to participate in scientific studies (left) and clinical trials (right)

3.2. Resistance to participate in scientific studies and clinical trials

Scientific studies

The total number of respondents to this question were n=52. Figure 2 shows that the main resistance factor influencing the non-participation in scientific studies was the lack of opportunity (86%), followed by the lack of time (6%) and “the fear of what could happen to me” (4%). “The fear that confidentiality and anonymization of my data are not respected” and “the lack of interest for the subject” both represent only 2% of the responses.

Clinical trials

The total number of respondents to this question were n=111. Figure 2 shows that the main resistance factor influencing the non-participation in clinical trials was also the lack of opportunity (69%), followed by “the fear of what could happen to me” (19%). The lack of time represented 6% of the answer followed by “The fear that confidentiality and anonymization of my data are not respected” (5%). The lack of interest for clinical trials represented 1% of answers.

Figure 2. Resistance to participate in scientific studies (left) and clinical trials (right)

3.3. Willingness to be informed about scientific and health research

78% of the participants expressed their willingness to be informed about scientific studies going on in Switzerland. Concerning clinical trials, 70% of participants expressed their willingness to be more informed. Regarding the willingness to be informed about the results of scientific studies, results are quite similar with 77% of positive answers. Concerning results of clinical trials, 71% of respondents answered positively. Regarding more information about ethical committee, 58% of respondents answered positively. 61% of respondents expressed their willingness to be more informed about data privacy management. Finally, regarding more information about data anonymization management, 60% answered positively.

4. Discussion and conclusion

The most frequent motivational factors to participate in scientific studies and clinical trials could be defined as altruistic motivations (e.g. help the science, the people concerned by the purpose of the study and the organizer of the study). These findings are in line with other studies demonstrating that altruistic motivations are the most important motivational factors in developed countries [1, 2, 5].

Individualistic motivations were rarely mentioned in our study both for scientific research and clinical trials, in contrary to other studies where financial compensation was the main motivational factor to participate in health research [7]. According to studies, low educational level and low socio-economic status and young age appear to have a positive link with financial incentives [7, 8]. Our finding can be explained by the high educational level (72%) of our respondents. The main factor influencing the non-engagement on scientific research or clinical trials was the lack of opportunity. This finding is in line with other researches [3, 9] and highlights the need to better inform citizens about ongoing studies. Moreover, the high percentage of respondents that would like to be more informed about ongoing studies, their results, data privacy management, data anonymization management and ethical committee, shows the poor communication between scientific community and citizens. The second factor influencing the choice not to participate in clinical trials was the fear of what could happen (19%), which was much higher than for scientific studies (4%). This result is in line with findings of other studies, underlining that the psychological or physical risks to enroll in clinical trials were one of the major reasons to decline participation [10-11].

It is therefore important to clearly explain the risks and benefits to participants in an understandable language intended for lay people.

Some limitations should be taken into account regarding the results' interpretation. The high frequencies of altruistic motivations compared to individualistic motivations may be partly due to the social desirability bias driving respondents to be viewed favorably [12]. Moreover, respondents were recruited using convenience sampling method (by physical location) during events aimed at raising citizen's awareness about science. This method may impede the generalizability of the results [13]. Also, the number of respondents who participated in clinical trials was low (n=11). Therefore, a broader study needs to be performed.

In conclusion, these results show that to improve citizen participation in scientific studies, the focus should primarily be put on communication to reduce the lack of opportunity. Being able to explain research and science better to lay people as well as the implications of participating in a study is crucial. New initiatives around general and dynamic consent could help to move forward on this topic.

5. Funding

This project is supported by the Swiss National Science Foundations 002632-000-BEHALF; the Swiss Personalized Health Network project 2017DEV 15 – C3Study and the Leenaards foundation project “smartConsent”.

Designing a Solution to Manage Electronic Consent for Children

Gary LEEMING,^a Sarah THEW^{a, b} and John AINSWORTH^a

^a*Centre for Health Informatics, Division of Informatics, Imaging and Data Science, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom*

^b*Storybook UX Ltd*

Abstract. Electronic systems for managing consent do exist but are generally only able to record consent from the research subject directly. Consent for research is also challenging to integrate into many electronic patient record systems. The Born In Bradford study is a large, from birth cohort study in the North of England which requires consent to be recorded by the pregnant mother of a child who will be included in the study from birth. This creates a complex challenge for consent management that has previously been achieved through paper-based processes. As the study begins a new phase with the objective of inviting all new parents within the Bradford region to participate in the study the solution also needs to work with existing maternity systems. This paper considers the specific challenges of converting the often grey rules around consent of children into an electronic system that is transparent and supports the trust of both the family and the clinical and care teams recruiting research subjects into a large cohort study, and describes the user centred design and technical approach taken to resolve it.

Keywords. Digital consent, User centred design, UCD, Electronic Patient Records

1. Introduction

The first Born In Bradford study began in 2010¹. Following its success, a second birth cohort study, Born In Bradford 2019² (BiB) began recruitment. BiB will give every mother in Bradford the opportunity to participate in a second cohort which will collect and link patient records from across NHS organisations for both mother and child, and also link to education and other data sources. The BiB team identified that continuing to use paper-based processes for collection and management of maternal consent would be impractical, but had not found a digital solution able to meet their requirements, such as easy integration with their electronic medical record (EMR) system and their existing research dataset. Most systems record consent either directly within the EMR (usually only for medical treatment) or within the study dataset, making it inflexible, hard to maintain and potentially lacking transparency. Consent by mothers for children, especially when planned over the lifetime of the child, is a relationship that must adapt to changes in the child's life. Connected Health Cities³ (CHC) was established to test learning health systems at scale across the North of England, and has worked with BiB 19 to develop a solution to address the complex consent management requirements of a birth cohort study.

2. Methodology

We adopted a user-centred approach to the design and development of the consent system. User centred design (UCD) is a collection of methods emphasising end users of a system and their goals, over the technology, and provide mechanisms for the users to be deeply involved in the design, development and testing of a system. A number of key principles inform this approach⁴:

Early focus on users and tasks: it was important for us to work with users to understand their existing and to-be working practices, environment, tasks and goals.

Empirical measurement: the testing and measurement of current performance, and throughput, e.g. numbers of births, recruitment rates, as well as testing of prototypes.

Iterative design - following cycles of investigation - design - build - measure. This approach fits well with Agile software development practices.

Our starting point was a project charter jointly developed by the teams from BIB and CHC, which set out key functional and nonfunctional requirements, including legislative and regulatory constraints. The project charter was used to derive a programme of UCD work: interviews and workshops with users to explore and document existing working practices, and develop a shared understanding of the requirements implied by the project's Standard Operating Procedures (SOPs.) We co-developed a series of artefacts:

- user stories to understand stakeholders' motivations, goals and context
- process maps to document current and future workflows
- system architecture diagrams, showing where different types of data would be stored
- low fidelity prototypes of user interfaces

These artefacts were used to support discussions with users, and iteratively updated to reflect our emerging joint understanding.

3. Consent Requirements and Implementation

Consent is a key component for people to be able to participate in research, as defined in the Declaration of Helsinki.⁵ BiB is a birth cohort study that does not involve a direct clinical intervention in the consented subject but consent for data access is still required. The guidance for consent of children from the MRC is that a legal guardian can provide consent for themselves and their children.⁶

The process for recruiting subjects into the BIB 2019 study has been to train midwives to discuss the project with all women during pregnancy and, if they consent, to record this within the maternity EMR. Only the mother or a guardian is required to provide this initial consent, which allows for both the mother and child's current and future medical records to be collected, de-identified and used in future research.

Understanding how to codify and implement complex consent requirements is challenging: developers do not have the detailed domain knowledge necessary, whilst the study team are used to working with paper or simple spreadsheets. An iterative UCD approach allowed us to jointly explore and resolve these challenges. Through the design process with stakeholders different requirements were mapped, including:

The data must be kept up to date and accurate. As far as possible the identity details, for example a person's address, are checked against hospital systems connected to the

NHS spine at regular intervals and also when the consent for a specific individual is requested.

The key for identity within the NHS is the NHS number. However, children are not given an NHS Number until they are born and so their consent and identity record needs to be directly linked to their mother and updated in the EMR, and then our consent store at the time of birth, once an NHS number is allocated. This is also linked to a birth order in the case of multiple births.

Children could be born out of area. This means updating of the child’s identity record will not be possible through the local hospital IT systems and must be manually investigated if the maternity record shows a pregnancy longer than 10 months (implying birth may have taken place out of area.)

Consent is given by mother for both herself and the child. Alternatively, a young or vulnerable mother may have a guardian who can give consent for the mother and her child. This means that both consents need to be managed, and the relationship between the consent owner and the child recorded. When withdrawing consent a later requirement was added to ensure that the person requesting the change and their relationship to the data subject is also recorded.

Mechanisms to request and integrate data from external agencies (e.g. education) must minimise the information shared externally.

Two types of withdrawal of consent that are defined. Firstly, a subject can ask to stop future data collection, but agree that existing data will remain within the cohort dataset. Secondly consent can be completely withdrawn meaning the collection of data is halted and the records associated with that consent are deleted.

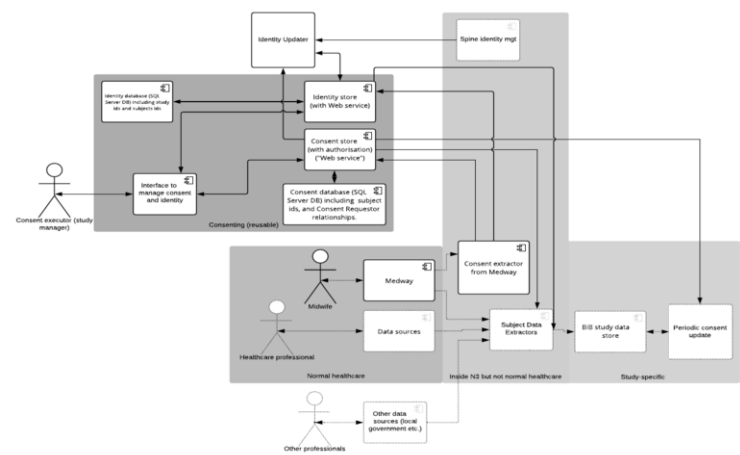

Figure 1. Consent Process Technical Scope including existing NHS systems, BIB 19 consent management and pseudonymised research datastores.

Other considerations include the death of a participating mother or child, and monitoring other changes in the child subject’s status, such as being taken into care. In this latter case the parents of the child may no longer have the right to give or withdraw consent. This responsibility is now that of the new guardian of the child. There is a further question as to when the child becomes responsible for consent and can be considered competent to manage consent for themselves. The age at which the child becomes solely responsible for their consent is defined as 16 although they do not need to be re-consented, in-line with other approaches and the Gillick test in the UK.^{7,8}

Where a guardian previously gave consent for the mother and her unborn child, when the mother reaches the age of 16 she must be re-consented.

The technical implementation of the consent model was based on two main data stores: Identity and consent in order to reflect the need to manage the relationships and consent through distinct mechanisms, as well as make it easier to logically separate identifiable data from the consent. Figure 1 describes how these data stores are managed and updated through a local administration web application, by the study team, and how it interfaces with numerous NHS systems to manage identity and provide core services for the pseudonymised research data set.

Once consent has been collected this gives permission for data to be collected about both the mother and the child. The processes for this data collection are currently in place within Bradford Teaching Hospitals NHS Foundation Trust and cover a variety of sources, including hospital and primary care medical records. This data is stored separately, in a de-identified format using a key linking to the original consent. The record of consent is regularly checked via an API that was developed to match a subjects' study id, and check any date constraints for consent. Standard Operating Procedures (SOPs) for managing consent have been developed and technical changes to the forms within the maternity EMR were agreed. The key requirement for the consent store is to enable the data management team to regularly check for changes in consent amongst the study cohort data in order to be able to update the research dataset.

Finally, there is a web-based administration application which enables the study administrators to manage subjects' details and consent preferences directly.

4. Conclusions and Challenges

The basic principles of consent are clear, but the numerous edge cases and changes to consent that can occur through a child's life present challenges in the design of a computerised consent solution for birth cohort studies. Furthermore, the translation of soft, paper-based processes to computer-based algorithms requires upfront discussion. Interpretation of rules and regulations that are not well codified is challenging, especially for consent for children, which can also vary between different jurisdictions.⁹ There are related challenges to guardianship, divorce, and changes in legal status. Using a UCD approach allowed the project teams to negotiate a joint understanding of these complex requirements, and provided users and developers with a clearer understanding of the implications of the legal requirements and study procedures on the architecture and software implementation.

Benefits include the ability to audit a complex area of consent more closely and simplified management of a large cohort. The solution integrates with the midwives' existing workflow and EMR systems, simplifying subject recruitment. The solution has been designed to be flexible and meet a wide range of edge cases, including integration with different EPRs and research data systems using APIs, making it flexible for the future. The code is made available under open source licence¹⁰ and continues to be improved based on users' feedback.

Working closely with the software team using UCD ensured that the platform met the requirements of the study team while also consulting other stakeholders, such as information governance, to provide a new type of consent management tool necessary for the scale, self-management and linkage of family and consent given for multiple

individuals. In order for this, or similar consent stores, to be able to deliver even greater value for research there is a need to define consent processes more precisely, especially consent for children, within ethical guidelines and law in order to be able to better codify and audit consent against best practice. This will be increasingly important with regards to international co-operation and standards for use of EHR data in research.

Acknowledgements

Born in Bradford is only possible because of the enthusiasm and commitment of the Children and Parents in BiB. We are grateful to all the participants, health professionals and researchers who have made Born in Bradford happen. The authors are also grateful to the staff at Bradford Teaching Hospitals NHS Foundation Trust and the development team David Kemp and Peter Crowther for their essential input into the project. Connected Health Cities is funded by the UK Department of Health and Social Care.

Effectiveness of Web Accessibility Policy Implementation in Online Healthcare Information

Muzawir ARIEF^{a,1}, Sari RISSANEN^b and Kaija SARANTO^a

^a*University of Eastern Finland, Department of Health and Social Management, Finland*

^b*University of Eastern Finland, Faculty of Social Sciences and Business Studies, Finland*

Abstract. UN have recommended the adoption of Web Content Accessibility Guidelines (WCAG) version 2.0 from W3C to guarantee that web content is more accessible to everyone. This study aims to evaluate the effectiveness of WCAG 2.0 implementation by comparing the country with and without WCAG2.0 policy adoption. The objective is to compare the impact of adopting the WCAG 2.0 standard in health information provision by analyzing the differences between countries that adopted the WCAG 2.0 standard and those that did not, specifically for health information related to the elderly. To this end, searches were performed on the Google search engine for online health websites with the keyword “Alzheimer” and the specific country settings for Indonesia and UK, in the local language of each country. Website evaluations were performed for ten websites found with this search by using the WCAG 2.0 measurement tool Axe. Statistical analysis using descriptive and Mann-Whitney analysis to measure the impact of the WCAG 2.0 showed a predominance of low violation occurrences in the UK with 40% from selected websites compared to 80% medium violation occurrences and no low violation occurrences in Indonesia. Although the country with WCAG 2.0 implementation had a lower frequency of violation, no significant differences were found between countries and the media type in WCAG 2.0 evaluation, implying the need to improve the effectiveness of policy implementation.

Keywords. Web Accessibility, Alzheimer, Policy, Online, Information

1. Introduction

Seeking health information online has become the most popular Internet activity among patients [1] and mobile phone users [2]. Previous studies have shown that the majority of people used commercial websites (71.8%), followed by search engines (11.6%), while only 5.5% use government websites for health information [3]. In addition, users with serious health problems and/or disabilities were more enthusiastic about online health information regarding their own health condition [4][5]. Previous studies have suggested that older people use the Internet the least due to many determinants such as age, physical limitation, education, social economic situation and social situation [6].

¹ Corresponding Author: Muzawir Arief, Dept of Health and Social Management, University of Eastern Finland, Kuopio Finland. E-mail: muzawia@uef.fi

Proper accessibility of online information related to health is a necessity for individuals who seek out health-related information due to their physical conditions.

Meanwhile, the World Wide Web Consortium (W3C) have designed the Web Content Accessibility Guidelines (WCAG) in collaboration with international figures and institutions to create international general standard of web accessibility that is suitable with any institutions, public and governments [7]. The guidelines have targeted web developers, web authoring tool developers, web accessibility evaluation tool developers, and others (individuals, decision makers, administrators, scholars. etc.) [7]. WCAG 2.0 has been approved as an ISO standard (ISO/IEC 40500:2012). WCAG2.0 encompasses web pages, web applications, mobile device applications, phones and tablets, digital TVs, wearables, devices in car dashboards and airplane seatbacks, household equipment, and other Internet of Things (IoT) [7], [8]. WCAG 2.0 have four accessibility principles: perceivable, operable, understandable, and robust, which must be fulfilled to avoid violations [9]. These principles have their own success criteria that determine the type and number of violations. The perceivable principle has 22 success criteria, the operable principle has 20, the understandable principle has 17, and the robust principle has 2. The UN prioritized web accessibility in resolution 61/106, and the standards have been implemented in their system [10]. With the resolution, access to information and communication technology have become basic human rights [11]. WCAG2.0 of W3C are the only internationally recognized standards [10]. Therefore some countries have ratified the standards following this UN recognition [12], [13].

This study aims to evaluate the effectiveness of the implementation of WCAG 2.0 in country with and without policy implementation. The study compared country that adopt the WCAG 2.0 standard in health information provision with the one that do not adopt the WCAG 2.0 standard to study the particularly of policy implementation on Alzheimer Disease (AD). To reach the aim, the study addressed two research questions (1) What is the level of web accessibility of AD-related information online both in the UK and Indonesia? (2) What are the similarities or differences in the information available online for AD between the two countries, one with a policy of accessibility (UK) and one without (Indonesia)?

2. Materials and Methods

Two countries were chosen for this case study. The United Kingdom was chosen for being a country that has adopted the WCAG2.0 standard [13], [14], and Indonesia was selected as a country that has not adopted the WCAG 2.0 standard. The selected countries were chosen also based on the first author language capacity. In addition, the idea to measure the difference have become consideration to choose the countries that are very contrasting based on their economy level besides the policy adoption. Web selection was based on the inclusion criteria of local language content: Bahasa Indonesia for Indonesia and English for the UK. It is important to note that the same word "Alzheimer" is used in both local languages to refer to AD [15]. The first ten websites from each country were picked based on their rank on the Google search engine list. The method for selecting the first ten websites has been previously used [16]. Google was first set up to the country-specific language, and a search was performed using the keyword "Alzheimer", due to its high frequent used among individuals searching for information related to AD [9], and it is known that AD affects cognition and memory [17], as consequences better accessibility of online information

is required. Among the obtained results, the website should be in a webpage format, and information from the same source will be excluded. The websites should have content related to AD, and the websites should not be from a journal publisher, university, or scientific research institution with the reason they are usually for academic community.

Website evaluations were performed for ten public online health information pages using the WCAG 2.0 evaluation tool recommended by W3C “Axe” [14]. In addition, Axe tool evaluate the website compliance to WCAG 2.0 with respect to WAI-ARIA (Web Accessibility Initiative-Accessible Rich Internet Application) 1.0 that is for assistive technology such as screen reader [18]. Based on the number of violations found, the website was assigned to one of four levels: low (0–20 violations), medium (21–50 violations), high (51–100 violations), and very high (above 100 violations). The term of violation means the unfulfilled WCAG2.0 criteria for accessibility for all. Statistical analysis was carried out using SPSS version 25. Descriptive and Mann-Whitney *U* tests were used to measure the differences between the two countries with and without WCAG 2.0.

3. Results

Entering the keyword “Alzheimer” for Indonesia and UK searches yielded 153,000,000 and 232,000,000 results, respectively. Using Axe tool analysis on the 20 websites (10 per country search), 17 types of violations were found. These were the violations found: (1) ARIA roles used must conform to valid values, (2) Elements must only use allowed ARIA attributes, (3) hidden ARIA element must not contain focusable elements, (4) Certain ARIA roles must contain particular children, (5) ARIA attributes must conform to valid values, (6) Buttons must have discernible text, (7) Element must have sufficient color contrast, (8) IDs used in ARIA and labels must unique, (9) ID attribute values must be unique, (10) Frames must have title attribute, (11) Html must have language attribute, (12) Image must have alternate text, (13) Form elements must have labels, (14) Links must have discernible text, (15) “ul” and “ol” must only directly contain li, script or template elements (16) Zooming and scaling must not be disabled, and (17) Timed refresh must not exist. Most website violations in the UK-specific search were under the low level category, whereas none of the violations in the Indonesia-specific search were of low level. Most of the tested websites in the Indonesia-specific search were found to have medium-level violations.

In addition, the 20 selected websites could be categorized into four types: non-government organization (NGO) websites (*n* = 5), medical related company websites (*n* = 4), newspaper-type websites (*n* = 10), and government agency websites (*n* = 1) (Figure 1 below).

Figure 1. Violation Occurrences Based on Website Type

NGO and government websites in the UK showed good compliance. Newspaper-type websites were the most common type of website for both countries. In the UK, two of the six newspaper-type websites with AD information showed good compliance with the standard and two showed a very high level of violation. On the other hand, all four online news websites in Indonesia showed medium-level violations.

The Mann-Whitney test revealed no significant differences between countries with and without WCAG 2.0 standard implementation. In addition, the most dominant type of violations found for both countries was “element must have sufficient color contrast” and “links must have discernible text.” Furthermore, “ID attribute value must be unique” was the third most violated standard in UK webpages while “image must have alternate text” was the third most violated standard in Indonesian webpages. A similar result was found when comparing newspaper-type websites and other website types.

4. Discussion

Implementing web accessibility policy globally continues to be a challenge. Despite national regulations, for example the United States Section 508 regulations requires every government agency to comply with web accessibility, accessibility problems persist [19]. In addition, the WCAG 2.0 policy has no impact outside government agencies [20]. Even within the municipal government, there are many issues such as national support and close collaboration across local administrators and external parties, citizen and other rules [21]. For example, although in the UK better accessibility was on the health administration agencies, only NGOs have slightly implemented better accessibility. Meanwhile, online newspapers were found to be the worst online channel in terms of adopting the WCAG2.0 standard.

The complexity in deploying WCAG 2.0 is elaborate, e.g., lack of law enforcement, no report or certification of WCAG 2.0 compliance, limited resources, policy content, lack of responsibility, and unclear guidelines from the department that

released the regulation [21], [19], [20]. The study revealed that the most common mistakes that should be easy to be understood, such as alternate text and color contrast in webpages still exist means whether web developers have reluctance to comply or excessive working load with short time due to particular business characteristic.

Another factor that might influence the evaluation is the richness of website content. It is known that the richer of the website content the more potential violation might exist.

Evolution of Interdisciplinarity in Medical Informatics in Europe: Patterns from Intertwining Histories

Casimir A KULIKOWSKI^{a,1}, George I MIHALAS^b

^a*Rutgers - The State University of New Jersey, New Brunswick, NJ, USA*

^b*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*

Abstract. The IMIA History project book we are co-editing with colleagues from the IMIA History Working Group includes histories of early contributions to medical and healthcare informatics, as described by a sample of pioneers and experts, detailing how their own ideas developed from their work on various topics in the field at the beginnings of their contributions to the field. Its contents serve as a preliminary guide for meta-analyses of how the different contributors state their personal interdisciplinary origins from today's perspectives. In this short article we provide a brief preview of how an analysis of disciplinary characteristics from individual histories can begin to shed light on processes of interdisciplinary evolution of medical informatics in Europe.

Keywords. Interdisciplinarity, History, Medical and Healthcare Informatics

1. Introduction

The history of science illustrates how the development of different disciplines and domains of study has almost invariably given rise to various “boundary sciences” or interdisciplinary fields in order to deal with problems through new approaches that draw from methods and threads of inquiry and experimentation from several existing disciplines. Such inter-weavings usually prove to be quite productive, yielding interesting new scientific discoveries or important technological and practical advances. A web of inter-relations between various domains frequently takes place, revealing sometimes-unforeseen links between apparently unrelated fields.

Usually, the very name of a new interdisciplinary domain tells us about its origin, specifying the “parent domains” whose intersection or blending has created the new discipline, as in biochemistry, psychopharmacology, and bioinformatics, among many others. This is also the case with medical informatics, which results from the intersection and interweaving of two very large fields of practice and study – medicine (relying on the biomedical and life sciences applied to healthcare) and informatics (relying on computer and mathematical sciences applied to information technology). Its name

¹ Corresponding Author, Rutgers - The State University of New Jersey, Piscataway, New Brunswick, NJ 08855, USA; E-mail: kulikows@cs.rutgers.edu

reflects its nature as an interdisciplinary field, or, as van Bommel stated: “medical informatics is interdisciplinary *avant-la lettre*” [1].

Studies on interdisciplinarity analyze various aspects of the links between concepts, knowledge and data structures or methods involved in the rise of a new domain. Such meta-analyses require a study and insight into the origins of the connections, which are not always presented clearly enough in the literature largely produced by authors from the existing disciplines. An incursion into a domain's history can cast some rays of light, revealing the roots of subsequent studies, which had strong follow-up and became substantive subfields of the new field.

2. Materials and Methods

We have recently carried out such a study, examining the roots of interdisciplinarity in medical informatics [3,4], based on 54 stories from European scientists who started their careers before 1980, or the early stage in medical informatics history, and which has been called its “pioneering period” [5]. The breakdown by length of experience in the field as measured from their year of university graduation consisted of 14 from 1960 and earlier, 20 from the 1961-1970 period, and 20 from 1970 to 1980. By gender, 48 were male and 6 were female.

We were interested in analyzing this data to uncover relations between the first professional background discipline of a pioneering investigator, through their professional affiliation, type of occupation or professional milieu within which the early medical informatics topics were approached (academic/university, healthcare organization, industry, other institution) and the medical informatics topics or approaches, both initial and subsequently developed.

3. Results

3.1. Professional Origins

Our study showed that 48 or about 81% of this sample of European pioneers in medical informatics had some kind of background involving technology or the exact sciences while 27 or 50% had backgrounds in medicine or the life sciences; with an overlap of 30% representing those who had a double specialization. Among the scientific or technical backgrounds, the most common were mathematics/statistics (19 persons), physics (13 total, but 10 of whom also had mathematics/statistics backgrounds also) and engineering (14 of which 7 involved computer science) but also chemistry/biochemistry (4) and biophysics (4). The biomedical profiles were predominantly in traditional medical specialties (20), while other fields included nursing (2), public health/epidemiology (2), dentistry (1) and psychology (1).

A obvious question that arises from this distribution of backgrounds is: “why is there such a high percentage of those coming from scientific and technical fields?” One might speculate that this might arise from an asymmetry that is observed in most interdisciplinary domains, including medical informatics, where one field provides the object of study (in this case biomedicine), while the others provide methods of analysis and interpretation (informatics). It has often been observed that those working in

information technology as researchers and scientists were able to foresee the great potential of computing technologies for various applications before the application-domain specialists come to fully realize and embrace it. The altruistic goals of medicine and nursing, and the desire to uncover the mysteries of life have led to a proliferation of several interdisciplinary fields, including medical informatics. Multidisciplinary teams have arisen, bringing together specialists from various fields trying to solve the complex problems that cross the boundaries between the more formal analytic disciplines, new technologies, and the field of medical and healthcare practices. But, to support effective collaboration and integration, specialization in a single domain is rarely enough. It is not a surprise that many researchers have felt the need for a double specialization. This has happened in both directions – medical and healthcare practitioners involving themselves in informatics and/or mathematics/statistics, while mathematicians, statisticians, engineers and computer scientists have in turn focused on biomedicine.

3.2. Occupational Backgrounds and Experiences

Most early medical informatics practitioners in our European sample (over 75%) were mainly academics who started their work within various departments of universities, with over 20% of them being from university hospitals; while others came from industry, non-academic hospitals or public health or research units.

It is interesting to note that we have found a large number (over 25%) involved in governmental activities or pan-European organizations. Indeed, the potential of information technology to be part of the process of improving healthcare activities often appear to have drawn the attention of official or governmental institutions (ministries or other healthcare authorities) from the earliest days of medical informatics.

The most frequent research activities involved coordinating or participating in various projects or acting as experts. Given the preponderance of academic affiliations, education and training was omnipresent, contributing significantly to the development of the field.

3.3. Subfields and Topics

One of the most interesting aspects of this first overview study drawing on histories of how experts developed their interests and contributions to the field has to do with the evolution of key problems addressed or topics defined: how the ideas evolved, what challenges presented themselves, and how they were overcome. Such inquiries are important since they better disclose the essence of those connections which motivate and build the effective interdependences and webs of interdisciplinarity. One can understand interdisciplinarity more fully as going beyond being just the passive application of methods from one field in a study to answer a direct question about some concept or object from another field. A simple statistical analysis of some clinical data can hardly be considered an interdisciplinary study. The substance of interdisciplinarity is a bilateral relationship between people from different disciplines who actively work together to ask new types of questions, with the goal of uncovering new features of a subject or object of study which can drive the development of new methods in order to reach a deeper understanding of the phenomenon being investigated. Such an approach was highlighted earlier by van Bommel in his detailed personal story [6], tracing the evolution of ideas in medical informatics as they changed over the course of his career.

In the present overview we use the four research challenge subfields or areas in medical informatics proposed by Kuhn et al. [6]: bioinformatics and systems biology, biomedical engineering and informatics, health informatics and individual healthcare, and public health informatics. As expected, since studies on bioinformatics and systems biology had barely started during the pre-1980 pioneering period we are examining, they represented only 5% in our sample, while studies on health informatics and individual healthcare are most plentiful, representing almost 45% of the total during this period. Studies in biomedical engineering and those on public health informatics had almost equal shares of approximately 25%, representing the disciplines that existed before informatics came to be defined as a separate field in its own right.

As discussed by Altman and colleagues recently [8], these subfields or areas of medical informatics interconnect at several levels and it is sometimes difficult to place studies in one specific group vs. another; so we have developed a number of criteria in order to do so, as discussed in more in detail in [3]. A better overall picture can be obtained by using a more granular, or refined breakdown of the areas or topics of study. The most frequently covered major topic out of a total of 65 was health information systems (28, or almost 20%), of which 14, or half, dealt with hospital information systems, with the others being clinical/laboratory or national information systems. The topic of data bases, most often associated with data processing or statistical analyses accounted for 15%, decision support systems including expert systems, AI and ontologies accounted for 10%, while electronic health records were the topic of another 10%. Remaining topics involved security and protection, standards and technological assessment, processing biological signals, medical imaging, modeling and simulation of pharmacological or biophysical phenomena, healthcare management and organizational impact, ethical issues and qualitative assessment studies, nursing informatics, clinical guidelines and telemedicine. Each were covered by a relatively small percentage of the persons involved in this sample from the early period of medical informatics research in Europe.

4. Discussion

Our study is preliminary, yielding just initial quantitative results, which, nevertheless point to how we can proceed with further more detailed follow-up studies. An important consideration is that personal narratives in free style do not lend themselves to the extraction of very precise data. Secondly, the professional backgrounds considered are very general and based on academic degrees or specializations, which does not characterize the important group of self-taught people, especially those who were self-instructed in the use of computers, which makes actual numbers of those with double specializations likely to be even higher than what is reported here. Since the boundaries between topics are not crisply defined; with some types of investigations distributed over several topics, the assignment of a study to a topic is not straightforward. Nevertheless, despite these limitations, the overall results are already quite suggestive about the patterns of backgrounds and interests of individuals, and their intertwinings, and correspond to the experiences of the authors in what they have observed over the years.

Some topics have persisted over time, remaining most relevant, or “hot”, either due to their generality, complexity and potential impact (artificial intelligence applications, the digital patient) or strongly determined by “external factors” (large healthcare information systems, requiring socio-economic and political involvement), or both (EHR

systems). Some topics have faded – such as biological signal analysis, where research has mostly migrated to specialized biomedical disciplines, or, once mature, to industrial/commercial development. Beyond the period covered by this analysis, totally new topics have arisen – having mostly to do with the internet, social media, privacy and security, patient empowerment, big data and, most recently, data science. These, while building on earlier methodologies and studies of the social impact of computers and information, have to confront completely new challenges of scale, complexity, and density of interactions in the evolving human-machine ecologies of today.

5. Conclusion

We can see from the histories or essays submitted to the IMIA history book that they give the reader selected glimpses of individual professional studies, investigations, and practices, which, taken together, allows us to begin to discern a map for tracing the ideas and practices of medical informatics history. A thorough analysis of the stories specific to various periods in medical informatics history, which will require careful definition and study, would yield a dynamic map representing “medical informatics in evolution” – a necessary enterprise which looks forward to more complete investigations and the involvement of new generations of biomedical and health informatics professionals.

Acknowledgements

The authors wish to thank the reviewers of the original submission for suggesting improvements. They also thank their friends in the IMIA History Working Group, the ACMI Committee of Historians, and other colleagues who have helped in the international biomedical and healthcare history projects related to this work.

^c*Auckland University of Technology, New Zealand*

Abstract. General Data Protection Regulation came into effect across the European Union in May 2018 but its implications in healthcare are yet to be fully understood. The aim of this study was to identify the fronts and hot topics in research on GDPR in healthcare. We analyzed the relevant records in Scopus through bibliometric and scientometric approach and visualization techniques. A set of 155 records was obtained and processed for co-occurrence analysis of key terms and concept mapping. The number of published papers showed a steep rise in the past two years, mainly by European countries. Analysis of the abstract of the papers showed that data protection, privacy, and big data were the most frequently used terms. Three dominant research fronts of GDPR are 1) general implications of GDPR, 2) technology aspects of GDPR, and 3) GDPR in healthcare service. Blockchain and machine learning are among the reemerging topics of GDPR research.

Keywords. GDPR, General Data Protection Regulation, bibliometrics, scientometrics

1. Introduction

With the proliferation of invasive digital technologies and the emergence of data-exploiting business practices, it is increasingly difficult for individuals to maintain control over their own personal data. Consequently, this issue of control over personal data has become a significant subject in European privacy law. Compared to earlier regulations, the General Data Protection Regulation (GDPR) explicitly addresses the rights of individuals concerning this issue [1]. This means that organizations are no longer able to use individuals' personal data without their consent. GDPR dictates that entities collecting and processing data related to European Union (EU) residents adhere to GDPR articles regardless of where these entities are located, or where the data is stored. GDPR compliance support the protection of privacy at various levels. Healthcare data breaches not only can affect substantial adverse personal and social impacts on patients, but also suffer a huge cost [2]. Most notably for the healthcare community, GDPR

¹ Corresponding Author: Farhad Fatehi, The University of Queensland, Brisbane, Australia; E-mail: f.fatehi@uq.edu.au.

explicitly introduces regulations for “data concerning health”, “genetic data”, and “biometric data” [3].

In spite of the fact that GDPR is a recently developed legal instrument, there have been many research studies on GDPR since its adoption in 2016, such as [4; 5]. Thus, it is important to identify and monitor the research fronts and trends relating to GDPR for better understanding and integration of this regulation with other security, privacy, and technological policies. Research fronts refer to the most dynamic research areas in science and technology that attract the most scientific interest [6] and are the body of articles that researchers actively cite in a short time span [7]. One main characteristic of emerging research fronts is high citation in a short time interval. The objective of distinguishing hot topics within a research front is to identify significant insights that are likely to determine the future direction of research. This study aimed to establish a GDPR research agenda by identifying the current trends, emerging research fronts, and hot topics in research on GDPR in healthcare using a bibliometric analysis approach.

2. Methods

We conducted a bibliometric and scientometric analysis of the papers that have discussed GDPR in healthcare. The data were obtained through an electronic search of Scopus database in October 2019. No limit on year of publication or language was imposed. The results of the electronic search were exported and loaded into Bibliometrix package for R v.3.6.1 and VOSviewer v.1.6.13 for bibliometric and scientometric analyses and visualization. [8; 9]. Research fronts and hot topics were identified by concept mapping of the abstracts as well as co-occurrence analysis of the keywords of each record. We used co-occurrence analysis of keywords to extract the topics of research and find the links between these topics directly from the content of abstracts. Sankey diagram was used to visualize the main items of three fields (i.e. Country, Keywords, Year), and how they are related.

3. Results

The first paper on GDPR in healthcare has published in 2012 and the number of publications was less than 10 per year until 2017, when it shows a radical increase up to 76 papers in 2018 (the year that GDPR was enacted). Germany has published the highest number of papers, followed by the UK and the Netherlands (Figure 1).

Figure 1. Countries with more than two papers based on the corresponding author’s address. (MCP: Multiple-country publication; SCP: Single-country publication)

A three-field Plot (Sankey diagram) of Country, Keyword, and Year of publication of the cited references was created to depict the proportion of research topics for each country and the recency of the papers that they cited. As shown in Figure 2, the main interests of GDPR researchers in France are big data and data protection. The dominant topic of research in the Netherlands is privacy. Most of the papers that discussed consent have published by Ireland, the Netherlands, and the UK. Research on GDPR and Blockchain, though are few in numbers, are mainly published by USA, Norway, UK, and Netherlands.

Figure 2. A three-field Plot (Sankey diagram) of Country, Keyword, and Year of publication of the cited references for the ten most researched topics.

The co-occurrence map of the most frequently used terms in the abstract of the papers was created to reveal the link between the terms and visualize the main clusters

Table 1. Research fronts and hot topics in GDPR research

Cluster (Color in Figure 3)	Research Front	Hot Topics
Cluster 1: Legal (Red)	General Implications of GDPR	Personal Data, Legal Aspects, Data Protection, Data Subject, Data Subject Rights, Data Access, Genetic Data, and Context-Specific Applications
Cluster 2: Technical (Green)	Technology Aspects of GDPR	Information Systems, Technology Solutions, Risks, Security, Controls, Timeliness of Data
Cluster 3: Health (Blue)	GDPR in Healthcare Practice	Patient, Patient Consent, Hospital Implementation, Health Data, Data Quality, and Use of Data

Prior evidence tells us that these dynamic research areas that create the greatest interest among the scientific community tend to be the most promising in terms of generating highly cited research, creating attitudinal change among researchers, challenging existing orthodoxies, anticipating possible paradigm shifts, attracting institutional funding, and enhancing the business value of the outcomes [4].

Researchers interested in data protection in healthcare can use our findings to plan for studies on the identified hot topics by observing the research trends, as well as research gaps in this domain. Likewise, journal editorial boards can benchmark their respective journals against these findings and introduce policies for publishing research on the increasingly important topic of personal health data protection. We believe Figure 2, in particular, reveals several opportunities for proposing special issues on important yet understudied topics, such as implications of GDPR for machine learning, Blockchain applications in healthcare, and ethics of collecting and processing personal health data.

Health ‘Big Data’ Value, Benefit, and Control: The Patient eHealth Equity Gap

Paul DEMURO^{a,1}, Carolyn PETERSEN^b, Paul TURNER^c

^a*Nelson Mullins Broad and Cassel, Fort Lauderdale, FL, USA*

^b*Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN, USA*

^c*eHealth Services Research Group (eHSRG), ICT, University of Tasmania, Australia*

Abstract. Improvements in artificial intelligence and machine learning combined with the availability and exponential growth in individual and population health data offer opportunities for innovative patient/citizen-centered eHealth solutions. However, this confluence of social, technical, and economic interests can result in the privatization of control of patient data and contribute to widening inequity in access to healthcare. This paper explores these issues and advocates for a more equitable approach to advances in health big data for patients and citizens.

Keywords. Health disparities, big data, eHealth, health equity, digital divide, artificial intelligence, patient-centered

1. Introduction

Recent developments in artificial intelligence (AI) and machine learning (ML) have combined with the availability of and exponential growth in individual and population health data to offer opportunities for new and innovative patient-centered eHealth applications [1] eHealth has been defined as “the cost-effective and secure use of information technologies (ICT) in support of health and health related fields [2]” mHealth may be seen as the use of mobile devices for medical and public health purposes [3]. This convergence has many positives, including strengthening the patients’ voice by enabling them to share data both with one another and with health professionals, which enables being more active participants in their own care [4].

Simultaneously, the health information technology (HIT) industry views health big data and patient-generated health data (PGHD) as an opportunity to generate value through the commodification of personal and population to generate value through the commodification of personal and population data aggregation, mining and exploitation. Opportunities for HIT to benefit from smart sensors, applications, and services abound as AI automates “datafication of health” [5], problematizes individual de-identification [6], and contributes to erosion of trust in health data sharing [7].

The capacity of the private sector to exert ever greater control over this big data aided by advances in AI and ML is little understood by individuals and policy-makers. It is evident that data commodification is occurring in ways that raise social, ethical,

¹ Corresponding Author, Paul R. DeMuro, Nelson Mullins Broad and Cassel, Fort Lauderdale, FL USA; e-mail: paul.demuro@nelsonmullins.com

and moral questions [8] and debate about value and benefit [9]. Failure to appreciate the implications of these technologies on health data hampers discussions about data privacy, data ownership, and consent for access and use of personal data. Given the pace of technological change, it is unsurprising that legal and policy frameworks, as well as mechanisms for their enforcement, remain inadequate. Technology-agnostic responses that meaningfully address data ownership, data protection, data retention and transmission, and data control processes are limited in scale and scope [10].

These socio-technical and economic developments may widen existing disparities in healthcare access between empowered and disempowered individuals and groups in healthcare access between empowered and disempowered individuals and groups [11]. Regardless of benefits that may accrue to some people, others are further marginalized. Many people lack the technical, health and genetic literacy to benefit from opportunities driven by big data and related patient-centered care models [12]. This paper explores these issues and advocates for a more equitable approach.

2. Background

Public and private health sector agencies are increasingly reliant on digital platforms for service delivery. These platforms are themselves become increasingly complex as AI, ML, and the Internet of Things (IoT) become embedded in HIT [13]. In combination, these developments mask the very real challenges that many individuals and groups face in accessing, using and benefiting from eHealth [14-16].

The General Data Protection Regulation (GDPR) provides for the protection of natural persons with respect to the processing of personal data and its free movement [17]. It applies to personal data relating to an identifiable person who can be identified in particular by reference to an identifier [18], such as those seeking health services.

Many patients find it challenging to understand how data held on them within eHealth systems is being managed, controlled, and valued. While many citizens believe that they own their data, numerous health entities – providers, institutions, HIT vendors, and third parties – may also claim ownership [19]. Although many patients may not own their electronic health record (EHR) [3], they should have to consent to its use and have access to it, as the GDPR provides for same [17]. Even when patients perceive that ownership of a digital device may support their claim to data ownership, others still may control and monetize that data [20], such as via control of PGHD that is accessible by device manufacturers, app developers, and third-party trackers [21].

In this context the eHealth inverse care law (the potential for meaningful use of appropriate eHealth is inversely proportional to the needs/capacities of the individual or population served) and equity gap become most evident [22]. Socially disadvantaged people are already known to be disproportionately affected by consent issues, and this is even more problematic in eHealth domain [23]. In the EU, however, such consent must be specific and informed, should cover all processing purposes [18] and requires a positive opt in [17]. Special category or certain sensitive data may be afforded more protection, e.g., in the healthcare context, genetics, biometrics, health, sex life, or sexual orientation [3], [17], [18]. Given that the GDPR is seen as more comprehensive than other such laws, including those addressing such issues in the United States, the GDPR provides for data protection in the context of international transfers where that is not deemed to be appropriate safeguards in those countries [17], [18]. Many digital

apps require high levels of technical and health literacy [24], which widens disparities within the eHealth ecosystems [25].

3. Data Sharing and Challenges for Patients and Citizens

There are huge opportunities and benefits associated with deployment of AI and ML into eHealth. However, the health care system needs a better understanding of how new technologies are best deployed. Equity, not equality, should guide roll-out and use.

Patient-focused eHealth technologies typically aim to obtain consent for data sharing in a “one-size fits all” approach that provides the same options to all users of the system. However, users have differing needs, experience, and skills, and few may experience equivalent risks when agreeing to secondary use of their data. Socially disadvantaged people are likely to be disadvantaged as users and sharers of personal health information, including PGHD.

The asymmetry of costs and benefits regarding data sharing has multiple aspects and, potentially, numerous adverse effects on health outcomes and quality of life. People with lower socioeconomic status may be less able to reap the benefits of treatments and products developed using PGHD shared by themselves and others. They may be unable to pay for care or medications, or may lack transportation to clinical sites where advanced treatments are available, or have greater difficulty understanding consent forms and digital products’ “Terms of Service,” and thus be at a disadvantage in making informed decisions and in advocating for themselves. Such asymmetry also may result in skewed research results affecting populations. For example, those with more education report greater willingness to sign up for biobank research [26-27], that may result in development of inaccurate clinical guidelines and ineffective policy-making that further extend eHealth inequities. The GDPR can provide some protections for covered individuals.

People who have uncommon traits may be identifiable if certain other pieces of information (e.g., birthdate, postal code) are known or can be located using public databases [28]. Even without the intent to share data without consent, the recurrence of data breaches leaves individuals exposed [29].

At the same time, individuals who have a high expectation of benefiting from research in which they participate will provide broad consent for use of their data in research without knowing exactly what that research will address [30]. Some expect min-health-specific benefits, such as improved patient-clinician communication [31], or view data sharing as a way to access better more personal information and care [32]. However, expectations of benefits cannot be guaranteed, and may contribute to the growing mistrust of healthcare organisations, clinicians, and the eHealth system. Although the GDPR provides some protections for secondary data use and the need for specific and informed consent, those who seek to benefit from such research may well interpret such protections broadly, such as contending that further processing of such data for specific scientific purposes is compatible with lawful processing operations.

4. Improving Use of Health Big Data for All Patients

Equity is about fairness. AI and ML have the potential to deliver precision medicine where “n equals you.” It is thus reasonable to require equity as a design principle for

new eHealth products and services so that patients and citizens can easily understand the benefits, value, and control of data manipulated by new tools and consented to their use when alone or in interaction with clinicians [33]. To reduce barriers, developers of mHealth apps, creators of health IT, policy-makers and researchers should consider citizens' psycho-social and economic contexts when using eHealth and avoid design that could compound disadvantage, bias, and inability to access resources.

5. Conclusion

This paper has highlighted how advances in AI and ML in eHealth may contribute to the privatization of control over patient data in ways contributing to widening inequity in access to healthcare. The paper has advocated for a more equitable and informed approach to emerging advances in health big data for all citizens.

Abstract. Modern research projects in healthcare research and medical research are oftentimes multi-centered, multi-disciplinary, and conducted by a consortium of multiple collaborators. Increasingly, the resulting data emanating emerging from different primary and secondary sources is linked on a personal level. The General Data Protection Regulation regulates many fundamental processes in such research projects. Despite the regulatory framework given, it can happen that a collaborator does not handle data properly. We propose a systematic risk management for the handling of data as well as a systematic error management.

Keywords. privacy, risk management, organization and administration, legislation and jurisprudence

1. Introduction

Benefiting from healthcare research, modern health information technologies can reduce human errors, improve safety, and thus refine the treatment provided to patients [1]. Aside from occurring during the delivery of care, human errors also ensue within healthcare research [2], inter alia when sensible data is processed in study projects. A common type of errors are *data breaches* when proprietary data is disclosed to an unauthorized viewer [3]. While this is not an immediate threat to most patients, the implications can be severe as well; sensible information mandates adequate handling [4].

Networked Healthcare research projects are conducted by a consortium of multiple collaborators. The data results from various primary and secondary sources and is linked on a personal level which opposes complete anonymization [5]. The handling of data relatable to a natural person is regulated by the *General Data Protection Regulation* (GDPR) [6]. The GDPR requires an effective risk management in the form of a *Data Protection Impact Assessment* (Article 34, GDPR [6]) and appropriate *technical and organizational measures* (Article 25 (1), GDPR [6]).

² Shared first Authorship

However, when working as a trusted third party in networked research projects, we frequently encounter situations in which proprietary data are not handled adequately. One collaborator sent Patient IDs to the wrong collaborator, another revealed a password in email conversations, and hospitals shared medical information together with identifying data. Many researchers seem to be insecure when handling data breaches that are caused by human errors. Contrary to breaches arising from cyber-attacks, theft, loss or data leaks, these are understood to be ultimately inescapable [1,7]. In the case that an error leads to a data breach, a systematic risk- and error management with appropriate counteractions is necessary.

Despite the regulatory framework given by the GDPR, there is no easy-to-use risk and error management framework to systematically aid researchers in the event of a data-breach. We provide an abstract case example, from which we start to discuss methods and strategies that can be used to avoid, and if necessary, address risks or errors occurring in healthcare research projects.

2. Method

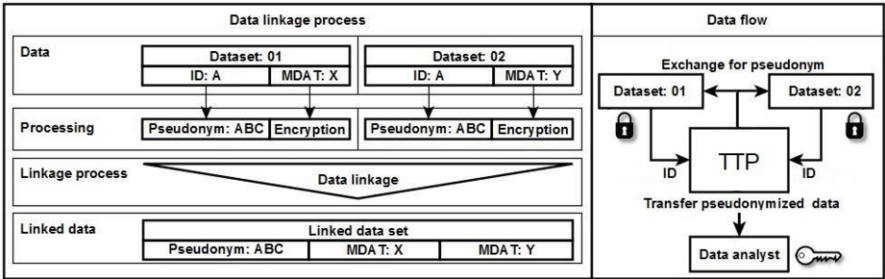

Figure 1: Data linkage process and data flow for the exemplary study design

We suggest tools to handle and prevent data breaches in health research projects when applying the current legislation regarding the GDPR in Germany [8]. Based on a generic study design, we discuss human errors and the compulsory risk management.

The exemplary research design is used to send two datasets collected by different collaborators via a trusted third party (TTP) to a third collaborator that evaluates the data. The TTP employs some method of data linkage to allow for the analysis of two medical datasets from two different sources (c.f. Fig.1). The datasets will be linked on patient-level through the pseudonymization of a project-wide, unique ID. This unique identifier could, for instance, be a case number identifying individual patients across datasets. The data is locally preprocessed with a software that encrypts only the medical data, not the ID. All processed datasets are then send to the TTP, which exchanges the ID for a new random pseudonym using a software that locally stores related IDs and pseudonyms. All data is then delivered to a data analyst as a file that contains data in a table-based structure. After decryption, each row contains medical data under the given pseudonym for analysis.

Human-induced data breaches in this context can happen during processing, data linkage, transmission or evaluation. One can discriminate three types of errors leading to a data breach event. Data can be (1) directly compromised (e. g. a screenshot of sensitive data in an email or data sent to an unauthorized person), (2) indirectly compromised (e. g.

not sufficiently pseudonymized) or (3) compromised due to misuse of technology (e. g. the wrong column in a dataset is pseudonymized).

For the assessment and handling of data breaches in such networked research, there are various laws to be considered. Aside from the GDPR, the BDSG, defines specific regulation for Germany. Processing of medical data for the purpose of research in both regulatory frameworks (Article 5, Article 9, GDPR [6]) and the BDSG (§22, §27, BDSG [8]). The GDPR requires a data protection impact assessment for data that could cause high risk to freedoms or rights of a natural person, and offers a minimum structure for such (Article 35 (1), (7), GDPR [6]). It is mandatory to employ *data protection by design* and *by default* similar to the *Privacy by Design* concept suggested by Cavoukian et al. [9]. The data controller (Article 4 (7), GDPR [6]) has to implement appropriate technical and organizational measures (Article 25 (1), GDPR [6]). Thus, the compromization of critical data requires the data controller to notify the responsible supervisory authority and affected persons within a determined period of time (Article 33, Article 34, Recital 85-88, GDPR [6]; §29, BDSG [8]).

Considering the GDPR, human errors have to be addressed on three levels; it is necessary to (1) work with adequate technical and organizational measures, (2) employ a systematic risk management, and (3) use an effective error management strategy

3. Results

Technical and organizational measures should render errors as unlikely as possible. State-of-the-art encryption and transport-encryption of all data are an indispensable prerequisite. In the context of the given example study, data need to be integrated button-up in the organizational design. Dataflow and software are usually designed with requirements engineering, so that it is –in theory– not possible to directly compromise data if software is used properly. Indirectly compromised data and the misuse of software have to also be addressed; the software in our example could check if the column containing the ID is not encrypted but the columns containing the medical data.

Direct and indirect compromization need to be conceptually addressed on an organizational level. Checklists and standard operating procedures (SOP) are generic methods to support processes. Checklists specify a set of goals to be fulfilled giving the user a framework to handle a specific process. The design of a checklist is challenging; a checklist must take the needs of different stakeholders into consideration and requires a careful mixture of guidance and independence, as not to limit people in their opportunity to make reasonable decisions [10]. SOPs give a detailed list of procedural steps which must be fulfilled. SOPs can be used for fixed processes that are repeated multiple times. In the context of our exemplary study, organizational measures would enhance and secure the project on working process level. SOPs would guide through the pseudonymization process, even when software is used. Another SOP would forbid workers revealing using the ID in email conversations. Checklists would offer the possibility to double check manually, whether the files have been processed according to the given framework conditions.

For a *systematic risk management* we adopted the HIT risk management concept from the IMIA Working Group for Health Informatics for Patient Safety [11]. During *Risk Assessment*, the risk of data breaches is analyzed and evaluated, *Risk Monitoring* serves as the instrument to identify data breaches and *Risk Control* comprises all counter

measures to manage data breaches on an operational level. Hence, risk management for data breaches is an iterative process resulting in continuous enhancements (cf. Fig. 2).

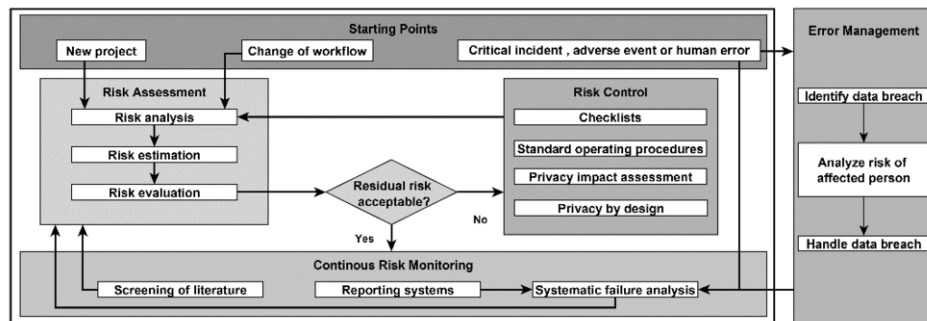

Figure 2: Systematic risk and error management of human-induced data breaches

Each error leading to a data breach has to be analyzed and handled individually as part of an *error management*. On an operational level, we suggest to divide error management into three generic phases and a subset of generic subtasks. The process should start immediately after the breach was discovered (Recital 87, GDPR [6]). In a first step the circumstances of current data breach are identified. It is crucial to categorize the compromised data in order to evaluate the risk. The GDPR defines different types of personal data into directly identifiable, pseudonymized, and anonymized [12]. In the second phase, the situation has to be evaluated in cooperation with the local data protection officer. The assessment of a risk for an affected person is the central process in handling data breaches. The target is to evaluate, if persons affected by the data breach will suffer a high risk in rights and freedom (Article 33 (1), GDPR [6]). If so, it induces a notification of the local authorities and the affected person. The notification should be made immediately and preferably within 72 hours (Article 33 (1), GDPR [6]). In the third phase, the actual data breach is handled by notifying authorities – if necessary – and isolating and deleting the compromised data. For the explicit procedure, the local data protection directives need to be considered.

What happens if the data analyst from our example received the full name of one participant and the respective ID when a data subject access request was handled? After identifying the data breach, she has to consult the local data protection officer to estimate the risk for the affected person. It is not mandatory to notify, when technical and organizational measures deny unauthorized persons access to the compromised data (Article 34 (3) (a), GDPR [6]). In our example this is the case, since the encryption denies the access to the medical data to any person except the data analyst; few people have access to the data and only the TTP can relate an ID to a natural person. Further, it is not obligatory to notify when the data leak will not result in a high risk to the rights and freedoms of data subjects (Article 34 (1), Article 34 (3) (a), GDPR [6]). If the data analyst analyzed the data breach, identified and isolated the compromised data, she can argue that the subsequent risk is low if the request containing name and ID is deleted (Article 34 (3) (a), GDPR [6]). We recommend documenting the data breach precisely; a controller has to be able to demonstrate a minimum risk (Recital 85, GDPR [6]). The consequential systematical failure analysis will then lead to a revision of potential SOPs for the handling of data subject access requests.

4. Discussion and Conclusion

Human-induced errors will always happen. We discovered the need for the development of adequate risk and error management in our everyday work. The framework of the GDPR gives room to interpretation and the legal space has yet to be embellished, which opposes easy handling of risks and errors. We developed a risk management concept and a protocol for error management giving guidance dealing with human induced errors and data breaches. Such a framework can prevent human-induced errors due to continuous learning and refined processes within distributed health care research projects.

The premise of all measures taken to reduce the consequences of human error is maximum transparency. A culture which facilitates the reporting of data breaches, which is the ultimate prerequisite for effective risk and error management, has been consensually established in medicine within the past decade [13]. However, it has not been translated to healthcare research yet. Reliability, safety, quality, and human factors are well-established fields in applied medicine and healthcare but not been applied on the level of healthcare research. A reporting system like the Critical Incident Reporting System (CIRS) [14] could be used to anonymously collect data of incidents and almost occurred incidents in order to establish an error culture. This data would contribute to developing and enhancing tools for a systematic risk- and error management.

Impact Analysis of the Policy for Access of Administrative Data in France : A Before-After Study

Vincent LOOTEN^{a,1} and Marie SIMON^b

^aUMRS 1138, Centre de Recherche des Cordeliers, Université de Paris, Paris, France

^bUniversité Paris-Est Créteil, Créteil, France

Abstract. In 2017, French institutions reformed their data access policy regarding the national insurance and administrative databases systems (French abbreviation: SNDS), including claims data from hospitalization discharge summaries for the entire population follow-up encompassing over 10 years. Our study aimed to quantitatively and qualitatively describe such authorization before and after the reform. We extracted data access demands for French National Health Data Institute (INDS) data before and after the reforms. We included only studies that needed data extracted from the SNDS database and authorization of the regulator. We inferred the number of projects accepted pre- and post-reform, and we describe the types of studies, their topics, and the types of data used. We included 802 data access demands between January 1st 2008 and September 21st 2019. The median of data access demands by year increased from 21.5 to 203. This increase was lower in the studies included insurance data (21.5 to 70). The evolution is driven by the activity of Private companies and contract-research organization. The number of studies on Hematology and oncology and internal medicine increased respectively by 1.7 and 1.4 factors. Data access of claims data refers to the “accessible” dimension of the FAIR guiding principles. However, extrinsic factors influence the accessibility of claims data such as human factors (e.g. data scientist with experience in claims data) and economic factors (e.g. data infrastructure HIPAA and GDPR compliant).

Keywords. [Data Sharing](#), [Policy](#), [Administrative Claims](#)

1. Introduction

Data sharing is a prerequisite for open innovation in health to produce reproducible research and to promote open science. Healthcare professionals and citizens need to be equipped to share data to facilitate scientific research and minimize the potential privacy threats[1]. Since May 2018, data sharing, including that of European citizens’ personal data, as well as data processing in the European Union, has been subject to the General Data Protection Regulation (GDPR)[2]. The GDPR provides a legal framework for data reuse and offers a chance to standardize data protection practices in research, as well as opportunities for researchers in medical informatics to develop new models for information technology infrastructure[3]. In 2017, French institutions reformed their data access policy regarding the national insurance and administrative databases systems

¹ Corresponding Author: Dr Vincent Looten, Université de Paris, Paris, France; E-mail: lootenv@gmail.com.

(French abbreviation: SNDS), including claims data from hospitalization discharge summaries for the entire population follow-up encompassing over 10 years. Researchers with access to the SNDS are producing studies on various topics such as patient care pathways, pharmacoeconomics, and pharmacoepidemiology[4]. The French reform for data access to SNDS aimed to open insurance data to a wider research community, including public and private research labs. The research community hypothesized that enforcement of the GDPR has impacted this reform's effects. However, to the best of our knowledge, no previous studies have described the 2017 reform's impact on data access authorization with regard to the influence of the GDPR. Our study aimed to quantitatively and qualitatively describe such authorization before and after the reform.

2. Method

Data sources. We extracted data access demands for French National Health Data Institute (INDS) data before and after the reforms. The data used in this study are available at www.github.com/vlooten/datapolicy, while more recent data can be downloaded from the INDS website (www.indsante.fr).

Inclusion criteria. We included only studies that needed data extracted from the SNDS database and authorization of the regulator. Projects that were resubmitted were counted only once (for the first submission).

Data access policy. Before the reform, a national committee evaluated submitted projects, and an approval from the French Data Protection Authority (CNIL) was required (i.e., two authorizations were required). After the reform, all projects following the CNIL national guidelines required just one authorization from a national committee. This committee checked concordance between objectives and methods, and compatibility of the study objectives with the public interest.

Outcomes and definitions. We inferred the number of projects accepted pre- (before August 1st 2018) and post-reform (after August 1st 2018), and we describe the type of investigator, the types of studies, their topics, and the types of data used. The type of investigators described were: (1) Government and agencies (2) Private companies and Contract-research organizations (3) Hospitals and care structures (4) Citizens and associations (5) Schools and research centers. The categories of the type of the studies were: (1) Descriptive and transversal studies (2) Longitudinal or prognosis studies (3) Pharmacoepidemiology, pharmacoeconomic studies (4) Economics studies (5) Other (included methodological and unclassified studies). The topics described were: (1) Cardiology and vascular medicine (2) Hematology and oncology (3) Internal medicine (4) Psychiatry and addictology (5) Public health and occupational medicine (6) Surgery (7) Primary cares and (8) Other (included unclassified and unknown studies). The types of data described were: National data with or without insurance data.

Statistical analyses. Data were expressed as number (%). Chi2 tests (for categorical data) was used to compare groups. All tests involved use of R 3.6.1(R Foundation, Vienna, Austria).

3. Results

We reviewed 2031 data access demands between January 1st 2008 and September 21st 2019. We included 802 data access demands according to the inclusion criteria. Reasons

of exclusions were: no pairing with national administrative data (N=1146) data access rejected or canceled studies (N=41), renew data access authorization (N=32) and missing data (N=10). Years of data access demands were: 2019 (N=203), 2018 (N=257), 2017 (N=74), 2016 (N=73), 2015 (N=61), 2014 (N=51), 2013 (N=24), 2012 (N=17), 2011 (N=19), 2010 (N=15), 2009(N=6) and 2008 (N=2). The median number of data access demands by year increase from 21.5 to 203. Table 1 presents the characteristics of the data access demands. We observed a difference between the two groups for the type of investigator. The number of access of private companies increases from 26 (8.87%) to 227 (44.6%), and school and research centers decreased from 98 (33.4%) to 59 (11.6%). We observed a change in the type of the studies with a reduction of Pharmacoepidemiology, pharmaco-economic studies (from 100 (34.1%) to 99 (19.4%). The structure of the topics also changes. In particular, the number of Hematology and oncology studies increased from 27 (9.22%) to 81 (15.9%).

Table 1. Description of the studies before and after the reform

	Before the reform (N=293)	After the reform (N=509)	p value
Insurance data	293	343	<0.001

Surgery	43 (14.7%)	25 (7.29%)	
Primary cares	12 (4.10%)	4 (1.17%)	
Other	11 (3.75%)	10 (2.92%)	

4. Discussion

Main results. To the best of our knowledge, we are the first to describe the effect of the French reform on the data access demands. After the reform, the median of data access demands by year increased from 21.5 to 203. This increase was lower in the studies included insurance data (21.5 to 70). The evolution is driven by the activity of private companies and contract-research organization. The number of studies on Hematology and oncology and internal medicine increased respectively by 1.7 and 1.4 factors.

Technical significance. According to the FAIR guiding principles[5] data must be Findable, Accessible, Interoperable and Reusable. Claims data have important intrinsic

characteristics in the FAIR perspective. Data access of claims data refers to the “accessible” dimension of the FAIR guiding principles. However, extrinsic factors influence the accessibility of claims data such as human factors (e.g. data scientist with experience in claims data) and economic factors (e.g. data infrastructure HIPAA and GDPR compliant). Two reasons could explain the most important demands of private operators: (1) the reform has reduced the time of treatment (only one committee compounded by specialists of data) (2) and the legal framework has been simplified ensuring a good visibility for elaborate business plans. However, the activity of the public sector has increased fewer; this could be explained by the absence of new data infrastructure and new funding strategy (extrinsic factors). In our perspective, the efficiency of a data access policy should be quantitatively and qualitatively monitored to understand the potential leverages of data reuse.

Remaining challenges. Schmidt *et al.* [6] have described the natural history of the data reuse in the Danish National Patient Registry. However, in the French context, data access demands database is not linked to scientific publications. A perspective of our work is linking data access demands and publication to describe the natural history of the French administrative data reuse. Data reuse of claim database has a natural history and this history is influenced by the data access policy.

Legal and Ethical Issues in Secondary Use of Administrative Health Data: The Case of Latvian Healthcare Monitoring Datalink

^bUniversity of Latvia, Faculty of Law

Abstract. The paper presents analysis of the legal and ethical issues surrounding establishment of the Latvian Healthcare Monitoring Datalink. The paper covers three interconnected issues in the context of the use of administrative health data for research purposes – anonymization of data, concept of ‘public interest’ and involvement of research ethics committees. The analysis has been put into broader context of interaction between General Data Protection Regulation (GDPR), national legislative measures and practical needs of researchers. Neither GDPR, nor Latvian legal framework regulate the particularities on the use of potentially identifiable health data in research. Also, the practical use of ‘public interest’ as a basis for lawful processing of personal data concerning health for research purposes is not clear. More extended involvement of research ethics committees might serve as useful tool for determination the ‘public interest’ and for the evaluation of proportionality when balancing the aims of the research and the personal data protection

Keywords. Personal data, data concerning health, secondary use, anonymization, informed consent, public interest

1. Introduction

To perform their functions, several state institutions in Latvia (the National Health Service, the Centre for Disease Prevention and Control, the State Emergency Medical Service and the Health Inspectorate) are collecting personalized patient level data. The primary use of these data does not require that the personalized data stored in one institution is linked to the data of the same person in another institution. Linking these data sets through a unique identifier for each person may ensure that the data can be used more broadly, e.g. for monitoring the quality and effectiveness of health care and for research. Joint initiative of the University of Latvia and the Ministry of Health of Latvia has resulted in development of a unique Latvian Healthcare Monitoring Datalink (Datalink) of unidentifiable persons and identifiable service providers [1].

The Datalink is controlled by the Centre for Disease Prevention and Control, and it includes healthcare process-related and outcome-related data of the population. The currently available data (2014-2018) includes information (health care provider, dates

¹ Corresponding author, Faculty of Medicine, University of Latvia, Jelgavas iela 3, LV-1004, Riga, Latvia; E-mail: juris.barzdins@lu.lv

of provided services, manipulations, primary and secondary diagnoses, costs etc.) about more than 65 million ambulatory and 3,5 million stationary treatment episodes as well as over 250 million units of medicines dispensed at pharmacies (including formulation, strength, quantity, and price). The demographic file provides information on patient's age, sex, place of residence. Additionally, the Datalink includes data from national Causes of Death Registry and from registries for particular diseases (e.g. diabetes, cancer) and conditions (e.g. trauma). The Datalink is updated once a year. To ensure protection of personal data, the direct identifiers of persons are irreversibly anonymized to exclude the possibility for either party to store and reuse the encryption key. Thus, to add data each year, the Datalink is re-created.

While the use of the Datalink for the monitoring of healthcare system performance by governmental institutions is regulated by the Cabinet decree assigning this function to the Centre for Disease Prevention and Control, the use of the Datalink for research is not clearly regulated by the existing regulatory framework leading to several legal and ethical problems. The present article addresses three of these issues – anonymization of data, concept of ‘public interest’ and involvement of research ethics committees.

2. Anonymized or potentially identifiable?

The data stored in the Datalink provides opportunity for researchers to analyse highly valuable administrative health data. However, due to gaps in legal regulation and due to ethical considerations, the secondary use of such anonymized but still potentially identifiable data is complicated. Some uncertainties arise also from the fact that the data originally have been collected for administrative purposes therefore there is no informed consent obtained for secondary use of the data in research.

The main scientific value of the Datalink is a possibility to track an anonymous patient's journey through the healthcare system knowing basic information about his/her health status, healthcare interventions and outcomes. The value of research data in many cases depends on keeping details regarded also as possible indirect identifiers as patient age, sex, place of residence, service provider, diagnosis, dates and codes for interventions. At the same time, the anonymization after linking independent datasets ensure privacy and confidentiality of persons concerned only if an indirect identification is not possible. It leads to the trade-off between the public interest justifying procession of such data for research and the small, but still existing risk of identification of persons.

Some, but not all aspects of this problem are regulated by the General Data Protection Regulation (GDPR) which does not apply to fully anonymized data concerning health but applies to pseudonymized and potentially identifiable data. Article 9 of the GDPR includes data concerning health into “*special categories of personal data*” for which there is a presumption that its processing is prohibited, at the same time, part 2 of the Article 9 provides a long list of exceptions on when the processing of special categories of personal data is permitted [2]. Mostly those exceptions are related to the consent of data subject or to the overriding public interest justifying procession of special categories of personal data. However, also in these exceptional cases, data processing must be legitimized by EU or national legislation and must be proportionate, including the duty of the data processor to take “*suitable and specific measures to safeguard the rights and freedoms of the data subject*” [2]. Article 9 (2) (j) of the GDPR includes a reference to the Article 89 explaining further

how to apply the above-mentioned conditions to processing special categories of personal data. Among other, Article 89 refers to the principle of data minimization explained in the Article 5, namely, that the data must be adequate, relevant and only include what is necessary for the purposes of the processing. The preamble of the GDPR also clarifies the processing of data concerning health for research purposes in several recitals. Recital 56 of the preamble refers to the main objective that justifies the processing of special categories of personal data, including data concerning health – it must be in the public interest. Recital 159 states that the processing of personal data for scientific research purposes should be interpreted in a broad manner including, for example, technological development and demonstration, fundamental research, applied research and privately funded research. While outlining the basic principles of data protection, the GDPR at various places points out to the responsibility of Member States to adopt further legislation, providing “*an unusually wide margin of maneuver for Member States*” [3].

In 2018 Latvia adopted the Personal Data Processing Law. Article 2 of this law puts forward the aim of the law “*to create legal preconditions for the establishment of the system of protection of personal data at the national level*” [4]. Regrettably, the new law is overly brief regarding regulation of scientific research. Although the law contains Article 31 on the processing of data for scientific or historical research purposes, in substance this article is just a blanket norm referring to the GDPR and copying Article 89 (2) of the GDPR.

Neither GDPR, nor Latvian legal framework directly regulates the use of anonymous or potentially identifiable health data in research. However, both the conditions for processing fully anonymous data and data anonymized but still potentially identifiable applies to the research use of the Datalink data.

3. Public interest as a basis for secondary use of administrative health data in research

One of the possible solutions is to use public interest as a basis for secondary use of administrative health data in research. The Article 9(2) of GDPR in listing possible grounds for processing of personal data not only includes a point (j) with specific reference to the “*scientific or historical research purposes*”, but also more general point (g) that allows processing of personal data “*for reasons of substantial public interest*”. The interrelation between those two grounds in the general scheme of the GDPR is rather unclear, especially considering recital 159 which states that “*scientific research purposes should also include studies conducted in the public interest in the area of public health*”. Yet, in any case, it should be possible to use public interest as a basis for secondary use of administrative health data in research, if all the preconditions on the proportionality, mentioned in the Article 9(2)(g) of the GDPR are fulfilled.

The problematical aspects of seeking the balance between public interest in research and privacy rights of individuals have already been analysed by several authors [5]. There are particular problems regarding application of proportionality test in cases when public interest serves as a basis for conducting the research, for example: how to define and assess public interest in the context of particular research protocol?

Assessment of the social value of the research study before it has been started is one of the main requirements in international documents defining the principles of research ethics for biomedical research involving human subjects. Human subject

research as defined in these documents is not only research where a person is directly involved in a study (e.g. clinical studies of medicinal products), but also research studies on identifiable human biological material and personal data.

Article 16 (iii) of the Council of Europe Convention on the Protection of Human Rights and Dignity in Biology and Medicine states that studies involving human subjects may be carried out only if *“the research project has been approved by the competent body after independent examination of its scientific merit, including assessment of the importance of the aim of the research, and multidisciplinary review of its ethical acceptability”* [6]. A detailed requirement to assess the social value of the study is included in the International Ethical Guidelines for Health-related Research Involving Humans issued by the Council for International Organizations of Medical Sciences (CIOMS) (2016). It states that *“[t]he ethical justification for undertaking health-related research involving humans is its scientific and social value: the prospect of generating the knowledge and the means necessary to protect and promote people’s health”* [7]. In Latvia, the Law on the Rights of Patients (Section 9, paragraph 8) allows research use of patient data recorded in medical documents without informed consent if several requirements are met, including the requirement that *“the study is carried out in the public interest”* [8].

At the same time, several questions arise in the context of these requirements, like: who and how should assess the social value of a research study? what exactly makes the study socially valuable? The practice shows that there is a need for criteria for assessing the social value of a study that could be used by research ethics committees and other bodies involved in the evaluation process. CIOMS guidelines state that *“The scientific and social value of research can be difficult to quantify, but it is generally grounded in three factors: the quality of the information to be produced, its relevance to significant health problems, and its contribution to the creation or evaluation of interventions, policies, or practices that promote individual or public health”* [7]. Ethicist Ezekiel Emanuel and colleagues have defined the social value of the study as the instrumental value of the new knowledge for improving human health. They clarify that the two main reasons for assessing the social value of a study by ethics committees are the prevention of harming study participants (including breaches of privacy) and the waste of limited research resources [9]. The accessibility and dissemination of the study results, including publication of negative results also is an essential pre-condition for ensuring the social value of the study.

4. New role for research ethics committees?

The GDPR in the Article 40 as well as in the Recital 98 encourages *“the drawing up of codes of conduct intended to contribute to the proper application of this Regulation”*. It leads to the role that research ethics committees might play in evaluation of public interest and protection of research participants. Currently in Latvia, the ethics approval for research protocols is clearly required by law only in few specific cases: clinical trials of medicinal products, clinical trials of medical devices and human genome research. For clinical trials and studies using data from medical documents mentioned in the Law on Patient Rights there is no legal requirement for ethics committee review.

This demonstrates the need for re-definition of the role of ethics committees in Latvia. The scope of research requiring review by research ethics committee must be broadened, because the current approach does not meet the requirements of

international documents on research ethics, as well as it does not ensure assessing of public benefit and protection of research participants for all types of medical and health research.

5. Conclusions

There are several ambiguities and problems in the context of establishing and use of the Datalink for the research purposes, which are not fully addressed by the existing legal framework in Latvia. First, it is not completely clear how to define and evaluate the public interest in the context of health research. Second, the line between fully anonymized and potentially identifiable data, as well as evaluation of risk of identification needs further clarifications. Third, there is a need to increase a role and involvement of research ethics committees in the review of secondary use of data concerning health.

The GDPR was one of the most important and most massive legal developments in the EU law of 21st century, ambiguities in the context of research in the field of data concerning health being only one small fraction of challenges that follows the GDPR. One can only hope that future case-law of the Court of Justice of the EU as well as additional national legislative measures will help to deal with those challenges.

Abstract. Finland is a world leader in the use of public electronic services. Continuous improvement to competencies is a prerequisite for the success of digitalisation in the service development sector. The increasing use of information technology in health and social care needs to be taken into account in the education of the health and social care sector work force. The mandate of the national SotePeda 24/7 project is to identify and define the informatics competencies required for multidisciplinary education of this sector in Finland. The project has adapted international recommendations for use in the national context. The national recommendation covers 12 areas of competency and related content. In addition to defining competencies, the project has produced a toolbox of materials for use by educators of these topics in universities that cover applied sciences and lifelong learning. The results of the project are expected to significantly improve the preparedness of graduating health and social care and related engineering and business sector students to make full use information technology, all of which benefits the national health and social welfare system.

Keywords. competence, skill, informatics, information technology, health care, social care, education

1. Introduction

Finland has the highest percentage of eHealth service users in the European Union (EU), (i.e., representing almost 50% of users). Generally, only 18% of EU citizens use online health care and social welfare² services [1]. A key objective of the National Finnish eHealth and eSocial Strategy [2] is to support the renewal of the healthcare and social welfare sectors. It emphasises the active role of citizens in maintaining their own well-being, which can be achieved by improving information management and increasing the

1 Corresponding Author, Tampere University, Hervanta Campus, Sähkötalo, FI-33014 Tampere University, Finland, Alpo.Varri@tuni.fi.

2 In Finland, 'social welfare' is social services, social assistance, social allowance, social loans and related measures intended to promote and maintain social security and the functional capacity of individuals, family and the community.

provision of online services; in this regard, the role of healthcare and social welfare professionals is crucial. A primary goal is that, by 2020, professionals in health care and social welfare will have access to information systems that support their work and its operating processes. The measures extend to national responsibility, for example, of training professionals in information management, as well as data entry, data protection, information security and knowledge management. The eHealth strategy of the Finnish Nursing Association 2015–2020 incorporates these objectives, with the aim of imparting competencies to nursing students in the use of technology, information literacy, knowledge management and informatics processes. These competencies will also be updated with supplementary training [3].

The increasingly widespread use of information technology [4] to support healthcare and social welfare professionals has created a need to improve informatics competencies in Finland. The Ministry of Education and Culture in Finland financed a national project, the Multidisciplinary Competencies for Health Care and Social Welfare Services in Finland (SotePeda 24/7) [5], with the primary aim of defining necessary informatics competencies and producing educational material for multidisciplinary use at the bachelor level education in the fields of health and social care and related engineering and business sectors of universities of applied sciences (UAS) in Finland. A secondary aim of the project was to support education that prepares students for work in a multidisciplinary team with a view to promoting the health and well-being of customers with the help of information technology. This paper presents how the competence definition work was carried out and what its present result is.

2. Method

The knowledge base for the descriptions of the competencies was primarily founded on international definitions of health informatics competencies in the Health Information Technology Competencies (HITComp) database [6,7]. The second version of the HITComp database which we used, is a result of the EU-US eHealth Work Project, an EU-funded project [13]. It was designed for educators, workforce developers, current and future workforce members, students, eHealth managers, staffing authorities, and others in healthcare information technology or eHealth [7]. Our project team used HITComp to search for competencies in a variety of healthcare roles. Competencies (i.e., ‘direct patient care’ and ‘administration’) were sorted into domains. The ‘basic’ and ‘baseline’ level competencies of HITComp were included for further elaboration. A healthcare professional with good knowledge of Finnish and English translated the competencies into Finnish and a group of health informatics professionals checked the correctness of the translations.

To adapt the list of competencies to the national context, the descriptions of the competencies also took into account the competence need findings of the latest studies in Finland based on a literature search. These included the Finnish Care Classification System [8], the eHealth Strategy of the Finnish Nurses Association 2015–2020 [3], the Nurses’ Competence Survey [9], national eHealth and eWelfare system (i.e., Kanta) documentation [10] and research into the competencies of healthcare professionals [11, 12]. The project team of around ten people, consisting mainly of experts in nursing but also participants with social welfare, health informatics and biomedical engineering backgrounds discussed the composition of competencies until a consensus was reached.

The HITComp originated descriptions of the competencies were grouped in the same way as those for the EU-US eHealth Work Project [13]. Areas of competence were initially described using a mind map, which made them clearer and easier to read. Finally, the mind-map was converted to a tabular form which then became the version 1.0.

3. Results

The produced list of informatics competencies required for healthcare and social welfare professional education in Finland can be seen in Table 1. HITComp terminology was used or adapted for the definitions.

4. Discussion

Although international recommendations for informatics competencies for health care professionals are available [6, 7, 14, 15], they are only applicable to a certain extent in Finland. A need remains to adapt the curricula to include components that support the national health care and social welfare environment and culture, as well as national strategic objectives [2, 3]. The competency definitions produced by the SotePeda 24/7 project [5] cater to these needs. For example, the proposed recommendations include social welfare-related competencies that are frequently absent from international recommendations, in addition to knowledge relating to the national health and welfare information repository, Kanta [10]. These recommendations also align with the Finnish eHealth and eSocial Strategy [2], which recognises that work is performed in multidisciplinary teams and sometimes includes business or technology professionals.

The SotePeda 24/7 project will reach completion at the end of 2020; until then, the work on definitions of informatics competencies continues. The 12 defined areas of competence will remain in the final version of competency recommendations. However, any additional feedback obtained from interactions with social welfare and health care authorities may necessitate minor improvements having to be made to the recommendations.

The proposed descriptions of the informatics competencies were valid at the time of writing. Digitalisation, innovations in information technology and new system implementations [4] will, however, necessitate updates to the descriptions from time to time. Each country should have a process in which competent professionals update the competence definitions. Finnish educational authorities on healthcare and social welfare informatics produced the recommendations, and the results will be followed and commented by authorities working in key healthcare and social welfare service positions and research institutions.

In addition to the competency definitions, the SotePeda 24/7 project is also responsible for the production of educational materials that support the educational approaches relating to these competencies. For example, one work package elaborates on educational materials about the ethical aspects of care digitalisation. Specifically, a toolbox has been developed for use by UAS educators (but potentially in other levels, too), who can select the materials and method of instruction of choice. The intention is

that the materials should support monological, dialogical and triological learning. The materials will be stored in a national repository of educational material.

Table 1. Definitions of health care and social welfare informatics competencies.

Area of competence	Main content
Basic information and communications technology (ICT) competencies	Information management and its tools, information and communication technologies and information literacy skills. Introducing new operating models, anticipating service and training needs, anticipating future digital literacy skills and motivation.
Online interactive competencies	Online dialogue with persons, changes in the roles of professionals, electronic communication environments, online meetings and consultations and the use of social media and online services.
Service competencies in digital health and the social care sector	Health and social care service structures, the usefulness of electronic health services, different electronic service environments and tools, the roles of social and healthcare actors, electronic service pathways, e-services and virtual reception.
Person-centred guiding competencies in a digital environment	Assessing customers' IT skills, IT guidance for customers, directing customers in search of information, supporting self-care by clients, the preparation of electronic guidelines, the production of online material, electronic outpatient clinics and information services, ie. chat rooms.
Competencies to monitor health and well-being in a digital environment	Artificial intelligence, sensors, robotics, wearable technology, utilities, various monitoring tests and instruments, monitoring information literacy and assessing the reliability and adequacy of information.
Health and social care informatics competencies	The interoperability of electronic systems, the communication of information via electronic information systems, electronic logging, national patient and social welfare data repository Kanta.fi, electronic data storage and roles and responsibilities regarding the use of information and legislation.
Multi-stakeholder service co-development competencies	Assessing the reliability of data sources, information management guidance and collaboration, privacy and security, co-operation and new operating models.
Ethical competencies	Ethical operating models and ethical competence in electronic services.
Service design competencies	User orientation, participation, innovativeness and new service pathways.
Knowledge management competencies	The use of monitoring and research data, customer- and patient-specific information, availability, quality and effectiveness of services (e.g., considering changing needs).
Research, development and innovation competencies	Assessment and continuous improvement of one's own skills, work community skills development, the development of electronic services, quality criteria for electronic services, the development of health and well-being technologies, exploitation of evidence-based information and an evaluation of effectiveness.
Societal competencies	Continuous consideration of information security in operations, the social impact of health technology on well-being and daily life, digital democracy and the promotion of social inclusion.

5. Conclusion

This project has significant national responsibility as it comprises recommendations on the healthcare and social welfare informatics educational material and curricula content of nursing students, other healthcare and social welfare professionals, as well as those in related fields (i.e., engineering and business) in UASs in Finland. As almost all UASs that offer this type of education in Finland are involved in the project, it is likely that the

recommendations will be followed at least to some extent. The educational material produced by the project will assist educators to introduce these topics to their students. The present version of the recommendations defines 12 areas of competence, the corresponding content of which is defined in detail. The recommendations are supported by a toolbox of educational materials to be used freely by educators in relevant fields in Finnish universities. It is expected that the recommendations and online educational materials will significantly improve basic healthcare- and social welfare informatics-related education in Finland.

SPHN - Development and Usability Testing of an Electronic General Consent Prototype

Julia MAURER^{a,1}, Ramon SACCILOTTO^a, Jörg WILLERS^a, Pascal DÜBLIN^a, Vu DUONG^a and Christiane PAULI-MAGNUS^a

^aDepartment of Clinical Research, University and University Hospital Basel, Basel

Abstract. Background According to the Swiss Law on Research in Humans, the reuse of routinely collected genetic and non-genetic data and samples from patients for research purposes requires the consent of patients. Unfortunately, the so far established paper-based processes are intrinsically linked to the hospital admission process, labour intensive and not yielding the targeted return rates. Therefore, the overall goal of the presented SPHN project is to increase patient reach by providing hospitals with a patient-centric, user-friendly and admission-independent electronic general consent pathway. As part of the project, feasibility of different digital pathways was evaluated in a usability testing.

Methods Based on a nationwide harmonised template, a mobile centric progressive web application was developed by the Department of Clinical Research Basel. Usability of the application and according user journeys were evaluated at all partner hospitals. Two options of giving consent were explored using 1) patients' smartphones without any involvement of hospital personnel and 2) a hospital device (tablet) with explicit confirmation of patient identity by hospital personnel. Participant signatures were captured as a picture of a handwritten signature on paper taken with the camera of the smartphone or tablet. Usability issues and feedback of participants were documented directly after usability testing.

Results In total, 122 users agreed to participate in the usability testing using a tablet or smartphone. The general consent request workflow on the smartphone or tablet was regarded as user friendly and easy to navigate by 96% of all participants. However, capturing a picture of a handwritten signature resulted in usability issues in multiple cases, i.e. due to missing pen or paper.

Conclusion Usability testing of our prototype application showed a broad acceptance of participants regarding the use of mobile electronic devices to give general consent. Therefore, we believe that easy-to-use digital general consent processes provide effective means to increase the patient pool for health-related research. Further discussions with legislative bodies are required to find patient centric, feasible and legally acceptable solutions in the specific case of electronic general consent for the near future.

Keywords. SPHN, personalized health, electronic general consent

1. Introduction

In Switzerland, use of routinely collected personal data (genetic and non-genetic) and biological material for research requires written consent of the affected person or the

¹ Corresponding Author, Julia Maurer, Department Clinical Research, Universitätsspital Basel, Schanzenstrasse 55, 4031 Basel; E-mail: julia.maurer@usb.ch

respective legal representative according to the Human Research Act (HRA) in January 2014 [1]. Today, all Swiss university hospitals have implemented rules and procedures to assure information of patients and documentation of consent in accordance with HRA requirements (so called «general consent process»).

Figure 1. Consent data from 2018 at the outpatient and inpatient sector of the University Hospital Basel.

Presenting paper-based consent forms to patients and collecting responses is labour intensive and comprises several individual process steps. Analysis of consent data from 2018 at the University Hospital Basel revealed that 36.7 % of patients in the outpatient and inpatient sector (47'290 out of 128'883) returned a decision. Of those patients, 86.1 % (40'718 out of 47'290) agreed to share their data and samples. As shown in Figure 1, 63.3 % of patients at the hospital where either not reached or did not return the general consent form. An internal survey revealed, that the situation is similar at all five Swiss university hospitals.

Predominant reasons for low return rates show the urgent need to develop additional, patient-centric and easy-to-use methods to inform patients and electronically collect general consent information. Furthermore, it is important to improve understandability of the general consent information employing visually appealing and interactive presentation that support patient understanding and satisfaction [2, 3].

Thus, the goal of the presented project was to evaluate the feasibility of an electronic general consent pathway through usability testing of a mobile prototype application.

2. Methods

A mobile progressive web application was developed by the Department of Clinical Research Basel as usability prototype based on the content of the harmonised national general consent template [4]. The aim was to find unforeseen issues with the consent workflow and user interaction when using the application in a real-world setting.

Two electronic general consent pathways were explored:

- a) Giving general consent using the personal smartphone without any involvement from hospital personnel. Identity of participants was verified by a token supplied through a mobile short message or email message for which participants provided the respective contact information themselves.
- b) Giving general consent using a hospital device (i.e. tablet) and manual confirmation of patient identity through hospital personnel.

Usability testing was performed at different settings (inpatient/outpatient), clinics and different patient population/participants (children/adults/elderly, male/female). Patients attending the hospital were asked by specifically instructed recruiters to participate in the testing. Participants using their own smartphone were provided with a language specific brochure containing a QR-code that could be scanned to directly access the mobile application website. In the case of hospital devices, hospital personnel would open the general consent website from a pre-installed app icon and hand it over to the patient. Visual features of the application were intentionally designed in close resemblance with hospital corporate design to establish a trust basis for participants. The landing page was presented in the same language as the brochure, with the possibility to choose a different language on request (DE, FR, IT, EN).

On a subsequent screen, the key points of the general consent content were summarized, followed by the full consent information as well as a hospital specific contact address for further information or questions. Participants would subsequently choose to agree or refuse the general consent and provide personal information (last name, first name and date of birth) with the option to specify a legal representative. In case of smartphone only use, identity was then confirmed via a token supplied by mobile short message or email for which participants provided the respective contact information. As a next step, participants would sign on the back of the brochure and capture the signature using the camera of the mobile device. Participants were then given the option to directly download a copy of the general consent or receive a copy via email. In case of verification through hospital personnel, participants would hand the device over to hospital personnel, to enter a secret division code, followed by manual confirmation of patient identity and manual electronic signature on the device. Evaluation was done on a pseudonymized dataset with anonymized participant comments.

3. Results

Usability testing was conducted from October 2019 until the end of 2019. All Swiss university hospitals and the University Children Hospital Basel agreed to participate in the usability testing at their institutions. A total of 146 participants were asked to participate. 122 participants (56 smartphone/66 tablet) completed the usability testing and subsequent questionnaire. The participant demographics were heterogeneous with a large age range from child to elderly. Reasons for non-participation varied from refusal and not feeling comfortable in participating to technical problems of not having a smartphone or missing internet connectivity.

In general, the electronic solution was well perceived by participants. On average, completion of the general consent process and usability questionnaire required approximately five minutes. Most participants agreed that the interface and the navigation was user-friendly. However, there were some issues regarding the signature workflow, mainly because participants did not have a pen at hand or had difficulties when taking a picture with the mobile device. In addition, participants criticized the amount of information which was provided as full consent text, «Too much to read»²,

² «Beaucoup à lire»

«Too much text»³ or «For me very comprehensible, but a lot – for people, not reading so fast, probably too much to read and too much to scroll»⁴.

Most usability testing participants were used to handle digital information on their smartphones or tablets. In addition, most participants did not have any concerns sharing personal information such as name, birthdate, phone number or email address as a mean to verify their personal identity. Perceived safety of the electronic consent process was high for both pathways (94%), but lower for smartphone users, where identification occurred via mobile short message / email verification only (89%). Respective concerns about data protection and the safety of an electronic signature in general were also raised explicitly by various participants, «Taking a picture of the signature does not appear to be safe»⁵, « I found the information that genetic analysis was being done somewhat frightening»⁶.

4. Discussion

Electronic general consent pathways build on the possibilities arising from digitalization, presenting information in more user-friendly and flexible ways.

An average completion time of five minutes and our own observations show that most users skip reading the full general consent text. This behavior is already known for the acceptance of general terms and conditions, nowadays a common pre-requisite for many online services. Feedback associated with length of text, indicated, that summary information with links to additional in-depth content would be perceived as more user-friendly and approachable. This could be even further improved by the use of interactive features such as dynamic infographics or video content, especially in the context of care for children and young adults.

Current legal requirements in Switzerland mandate a written consent for the use of data for research purposes (HRA Art. 16). Due to a missing definition of «writing» in this context, there is an ongoing legal debate whether consent has to be given in the form of a handwritten wet-ink signature or whether other means of «written consent» would be applicable. Usage of electronic identities and qualified electronic signatures would provide a legally equivalent digital process to a wet-ink signature [5]. Unfortunately, the implementation of electronic identities in Switzerland is still in its infancy and not a feasible solution in the near future.

The presented approach with a paper-signature and subsequent digitalization in the form of a photography is clearly not suited in terms of usability and legal aspects. However, general consent is used for the re-use of data and samples constituting a substantially lower risk compared to a study specific informed consent. Consequently, a less rigorous form of written consent – i.e. a handwritten signature on a mobile device – could provide a viable solution for general consent, if coupled with a reliable form of patient identification, such as verification through hospital personnel or biometric identification measures.

³ «zu viel Text»

⁴ «Für mich sehr verständlich aber viel - für Leute, die nicht so schnell lesen wohl zu viel und auch zu viel zum Scrollen»

⁵ «Das Fotografieren der Unterschrift erscheint mit nicht ganz so sicher»

⁶ «Die Information, dass genetische Analysen gemacht werden fand ich etwas beängstigend»

5. Conclusion

Further discussions with involved legislative parties are required to find legally acceptable, feasible, and easy-to-use solutions in the specific case of electronic general consent for the near future. Once the solutions are feasible at daily hospital business, we believe that a digital general consent process has the potential to further increase the pool of health-related routinely collected patient data and leftover samples available for further research projects.

Acknowledgements

This project was supported by the Swiss Personalized Health Network (SPHN) initiative (Grant number: 2017DEV04). We thank our collaborating partners Francisca Jörger (University Hospital Zurich), Alex Leichtle (University Hospital Bern), Marc Pfister (University Children's Hospital Basel), Cindy Roth (University Hospital Lausanne), Caroline Samer (University Hospital Geneva) and their teams for their contribution. We also thank Annette Magnin (Swiss Clinical Trial Organization (SCTO)), Klara Posfay-Barbe (SwissPedNet) and Christine Currat (Swiss Biobanking Platform) for their support.

SPHN – The Swiss Personalized Health Network Initiative

Adrien K. Lawrence^{a,1}, Liselotte Selter^a, and Urs Frey^{a,b}

^a*Swiss Personalized Health Network, Swiss Academy of Medical Sciences, Laupenstrasse 7, 3001 Bern, Switzerland.*

^b*University Children's Hospital Basel (UKBB), Spitalstrasse 33, 4056 Basel, Switzerland.*

Abstract. The Swiss Personalized Health Network (SPHN) is a national initiative designed to promote the development of personalized medicine and personalized health in Switzerland. SPHN contributes to the development, the implementation, and the validation of coordinated infrastructures in order to make health-relevant data interoperable and shareable for research in Switzerland. To this end, SPHN rallies all decision-makers from key clinical, research-, research support institutions and patient organizations around the same table.

Keywords. SPHN, personalized health

1. Introduction

Given the tremendous amount of health data available, health care and medical decisions should no longer be solely based on population averages, but take into account individual patient characteristics, including the variability in genes, molecular biomarkers, environment and lifestyle. To leverage the immense potential of these data for better prevention, improved medical practice and the development of innovative treatments, transdisciplinary scientific research, as well as specific infrastructural efforts are necessary: Health data need to be interoperable and broadly accessible for research according to the FAIR principles [1]. Additionally, research involving sensitive human data demands potent IT infrastructures that permit the collection, storage and analysis of high quality data, adequately link to biobank samples and, at the same time, fulfill stringent data protection and information security requirements. Furthermore, patients and citizens have to be included, not only for consent to release their data or samples for use in research, but also as active partners supporting research and helping to advance medical knowledge. These issues raise unprecedented ethical and legal (e.g., data protection) questions that must be considered even more within an extended personalised health ecosystem [2].

Although the public Swiss healthcare system is universal, healthcare is provided by a combination of public, subsidized private and totally private systems, and is organized largely on the level of individual cantons. To a large extent, this federalist principle until now prevented a nationwide coordination and/or harmonisation of

¹ Dr. Adrien K. Lawrence, Swiss Personalized Health Network, Swiss Academy of Sciences, Laupenstrasse 7, 3001 Bern, Switzerland; E-mail: a.lawrence@sphn.ch.

biobanks, electronic clinical information systems and clinical data management infrastructures and created a heterogeneity of health data infrastructures which has retarded the development of a nationwide personalised health ecosystem as compared to countries with more homogenous national health systems. These deficiencies have been realised early- on and appropriate initiatives have been undertaken on local and regional levels. In order to expand the local initiatives to the whole of Switzerland and complement them with nationwide efforts for making health data findable, accessible, interoperable and usable for research (FAIR) on a national scale, the Swiss Government launched the Swiss Personalized Health Network (SPHN) initiative in 2017. The mission of the initiative is to contribute to the development, the implementation, and the validation of nationally coordinated infrastructures which are required to make health-related data interoperable and shareable for research in Switzerland. Given its high quality health care network and excellence in research and technologies, Switzerland has the potential *to become one of the European leaders in health and medical science*, although the regulatory aspects of the federated health system are a major challenge for big data research. The initiative shall thus help to push Switzerland to the international forefront of personalised health-related research and health care.

2. Mandate and governance

The Swiss Personalized Health Network (SPHN) is an initiative of the Swiss federal government, namely the State Secretariat for Education, Research and Innovation (SERI) and the Federal Office of Public Health (FOPH). SPHN is led by the Swiss Academy of Medical Sciences (SAMS) in collaboration with the Swiss Institute of Bioinformatics (SIB). A total of CHF 68 million was allocated to the initiative for the first funding period 2017-2020. As defined in the corresponding mandate, the long-term goal of the SPHN initiative is to establish a Swiss network in personalized medicine, in which all relevant research institutions and hospitals in this field are involved. The development of a nationally coordinated data infrastructure including interoperability of local and regional information systems in order to optimize the use of primarily clinical but also other health-related data for research in the field of personalized medicine, is the central focus of the first funding phase. Rather than building a new centralized database, SPHN adopts a decentralized approach and aims to establish interoperability of health-related information by building a dynamic scalable network of data providers based on common standards for formats, semantics, governance, and exchange mechanisms. It is therefore our mission to lay the foundations needed to establish a nationwide exchange of health-related data for better disease prevention, improved medical practice and ground-breaking innovative treatments, transdisciplinary scientific research, as well as specific infrastructural efforts.

The SPHN project organization involves partners at national level, at technical level, and at institutional level (Figure 1). SPHN rallies all decision makers from key clinical, research and research support institutions around the same table. The combined knowhow, experience and commitment of the numerous partners and experts of the SPHN Boards and Working Groups enable discussion, collaborations and progress.

The National Steering Board (NSB) is the highest body of SPHN and is responsible for the overall strategy, for maintaining regular contacts to the superordinate political authorities and for external communications in coordination with the Swiss Academy of Medical Sciences (SAMS). The NSB includes representatives from key institutions in

Switzerland (e.g. University Hospitals, universities, ETH-Domain, swissuniversities, FOPH, SNSF, patient organisation). In addition to the NSB, SPHN is composed of the following Expert Advisory Groups/Bodies:

- ELSI Advisory Group (ELSIag).
- National Advisory Board (NAB, foreseen in 2020).
- International Advisory Board (IAB).
- Data Coordination Center (DCC) including several technical Working Groups (operated by the Personalized Health Informatics Group of SIB).

SPHN is further supported by the expert knowledge of several mandated SPHN *ad hoc* Working Groups, which are responsible for solving specific issues related to infrastructure development. SPHN has put very strong efforts into close collaboration with other stakeholders from the biomedical research landscape. This includes funders such as the Swiss National Science Foundation (SAKK) or the ETH Domain Personalized Health and Related Technologies Program (PHRT), and also research networks such as the Swiss Group for Clinical Cancer Research (SAKK), the Swiss Biobanking Platform (SBP), the Swiss Clinical Trial Organization (SCTO), as well as patient organizations (e.g. ProRaris, for rare disease). During the last years, these organizations managed to identify common issues and obstacles, which need to be addressed. Typically, the above-mentioned Working Groups are now highly coordinated within these stakeholder groups.

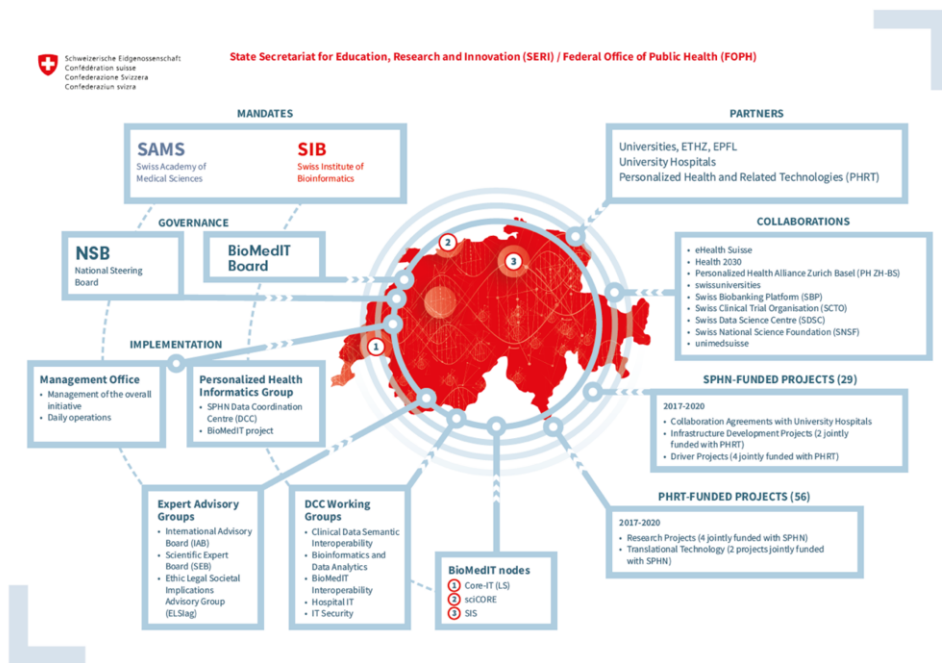

Figure 1. SPHN Governance.

3. Implementation

The SPHN initiative supports the development and implementation of coordinated infrastructures by means of a 3-pillar funding strategy:

1. **Top-down:** funding of compatible data management systems in the University Hospitals through Collaboration Agreements, as well as the SPHN Data Coordination Center (DCC) and ELSI projects.
2. **Bottom-up:** selection of projects through competitive Calls for Proposals to lead the development of infrastructures and test it with concrete research questions (Infrastructure Development Projects and Driver Projects). In 2017 and 2018, two SPHN Calls for Proposals were organized in close coordination with the Strategic Focus Area 'Personalized Health and Related Technologies' (PHRT) of the ETH Domain. Selected from a total of 76 proposals requesting CHF 90.4 million, SPHN funded 24 projects (incl. 6 co-funded by PHRT) for a total amount of CHF 25.3 million during this funding period.
3. **IT infrastructure networks:**, a secure and cutting-edge IT environment (BioMedIT, a project of SIB) is established to support computational, biomedical research and clinical bioinformatics, ensuring data privacy [3].

Further information on the projects is available on the SPHN website (www.sphn.ch).

The SPHN Management Office (MO) together with the SIB Personalized Health Informatics Group (PHI) are responsible for successfully implementing the mandate of

SPHN. The MO manages the daily operations of the initiative, coordinates the funding and ensures a good governance. The PHI group is in charge of the Data Coordination Center and the BioMedIT project.

To ensure nationwide interoperability of biomedical data, a variety of technical, ethical and legal issues have to be tackled. The ELSIag is responsible for the ethical and legal questions related to SPHN activities. The technical aspects related to the development of coordinated infrastructures, compatible data management systems, interoperability of data, and governance of guidelines, are tackled by the Working Groups of the Data Coordination Center in collaboration with the University Hospital IT teams.

4. Conclusion and Outlook

The SPHN funded projects involve 35 Swiss organizations and institutions which demonstrate the magnitude of this national endeavor. Over the past years, we have identified several key success factors for the development of a nationwide network such as i) the need for a common understanding of the vision and scope; ii) commitment of all players to share health data for the benefit of society (citizens, patients, hospitals, research institutes, etc.); iii) a transdisciplinary approach between clinicians, researchers, bioinformaticians, machine learning experts, etc.; iv) nationwide interoperability of health data and nationally coordinated data infrastructures; v) process innovation in research and health care; vi) dialogue with citizens and patient groups; and vii) transparent communication concepts to enhance public trust.

A review of the overall progress of the initiative and gap analysis was performed in 2019 based on the first project progress reports and an external international review by the SPHN International Advisory Board (IAB). As a result from this first evaluation, the biggest achievement of SPHN during the past years is probably the increasing awareness of the systemic gaps and problems related to the field. Though the initiative is overall on a good track and has made significant progress, the gap analysis revealed significant obstacles and hurdles. Most of them related to the federated health care system and the strong local awareness and particularities of data protection issues as well as ethical and legal priorities. In order to achieve interoperability, these issues, priorities and policies need to be coordinated on a national level. Here, the willingness of the stakeholders to agree and implement common strategies, standards and guidelines is a prerequisite. The political discussion needs to be initiated whether or not this should be enforced.

SPHN/PHRT – MedCo in Action: Empowering the Swiss Molecular Tumor Board with Privacy-Preserving and Real- Time Patient Discovery

Jean Louis RAISARO^{a,1}, Juan Ramón TRONCOSO-PASTORIZA^b, Sylvain PRADERVAND^a, Michel CUENDET^a, Mickael MISBACH^b, Joao SA^b, Francesco MARINO^b, Nicolas FREUNDLER^a, Nicolas ROSAT^a, David CAVIN^c, Alexander LEICHTLE^d, Jacques FELLAY^{a,b}, Olivier MICHIELIN^a and Jean-Pierre HUBAUX^b
^a Lausanne University Hospital; ^b EPFL ; ^c Geneva University Hospital; ^d Bern University Hospital

Abstract. MedCo is the first operational system that makes sensitive medical-data available for research in a simple, privacy-conscious and secure way. It enables a consortium of clinical sites to collectively protect their data and to securely share them with investigators, without single points of failure. In this short paper, we report on our ongoing effort for the operational deployment of MedCo within the context of the Swiss Personalized Health Network (SPHN) for the Swiss Molecular Tumor Board.

Keywords. SPHN, personalized health, privacy, security, oncology, data sharing.

1. Introduction

Although within Swiss Personalized Health Network much effort is currently being put into data interoperability and integration, data privacy and security represent important challenges that, if overlooked, can potentially hinder or even block the access and use of this data across the different hospitals. To tackle these issues, researchers from the Swiss Personalized Oncology project and the Data Protection for Personalized Health (DPPH <https://dpph.ch>) project have joined forces. The intention is to work together towards the development and the adoption of cutting-edge privacy-preserving solutions for data analytics that provide strong and long-lasting protection guarantees for patient data.

2. The Swiss Molecular Tumor Board Use Case

As a first step in this direction, the idea is to empower the Swiss Molecular Tumor Board (SMTB), which is meant to be a reference for the entire country for analysing complex cases and identifying the best personalized treatment, with MedCo, the first privacy-

¹ Jean Louis Raisaro, Lausanne University Hospital (CHUV), Chemin des Roches 1, 1010 Lausanne, Switzerland ; E-mail: jean.raisaro@chuv.ch.

preserving tool issued by the DPPH project that is co-developed by EPFL and the Lausanne University Hospital (<https://medco.epfl.ch>). MedCo [1] is a data discovery system that enables a researcher or clinician to securely perform, through a user-friendly graphical interface, exploratory queries (SQL-like queries for simple statistics) on encrypted clinical and molecular data that are horizontally partitioned across different hospitals. By relying on state-of-the-art technologies for information security such as homomorphic encryption, secure multi-party computation and differential privacy, MedCo ensures (1) that patients' individual-level data are protected against illegitimate access by unauthorized people, (2) that no single authority has to be trusted for the security of the data and (3) that the re-identification risk is minimized.

Our goal is to deploy MedCo at all the University Hospitals in order to enable the SMTB to make more informed treatment decisions (Figure 1). MedCo will offer experts of the SMTB the possibility of obtaining, in real time, simple statistics and aggregate information about treatment and outcome for patients with a similar clinical and molecular profile to the ones under evaluation (e.g. overall survival, overall response rate, progression-free survival). At the same time, the use of MedCo will ensure that the privacy of both the patients in the hospitals and the patient presented at the SMTB is preserved. To securely identify similar patients, MedCo will perform an encrypted search over all the oncology patients whose data is stored encrypted in the MedCo databases that are distributed across the five Swiss University Hospitals and then compute the requested aggregate information directly on the encrypted data of the identified patients.

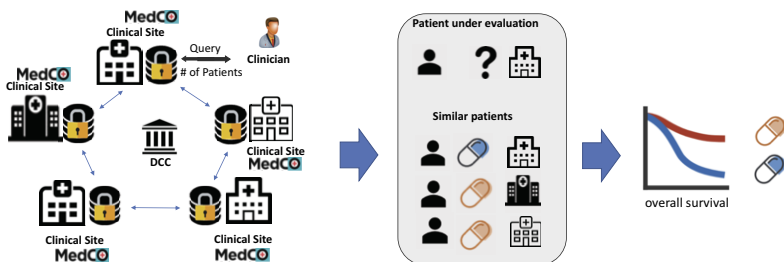

Figure 1. Envisioned use of MedCo in the Swiss Molecular Tumor Board. DCC: Data Coordination Center

3. Conclusion

MedCo will be initially deployed in the University Hospitals of Bern, Geneva and Lausanne for testing purposes. Once the data loading process, the governance and the functionalities of MedCo will be validated by the SPHN Data Coordination Center, the deployment will be extended to the University Hospitals of Basel and Zurich and the other hospitals members of the *Swiss Group for Clinical Cancer Research*, eventually.

Abstract. Sepsis is a highly heterogeneous syndrome with variable causes and outcomes. As part of the SPHN/PHRT funding program, we aim to build a highly interoperable, interconnected network for data collection, exchange and analysis of patients on intensive care units in order to predict sepsis onset and mortality earlier. All five University Hospitals, Universities, the Swiss Institute of Bioinformatics and ETH Zurich are involved in this multi-disciplinary project. With two prospective clinical observational studies, we test our infrastructure setup and improve the framework gradually and generate relevant data for research.

Keywords. SPHN, personalized health, sepsis, big data, diagnostics, digital biomarker, -omics biomarkers, machine learning, data exchange, interoperability, interconnected.

1. Introduction

Sepsis is a highly complex, life-threatening syndrome that develops when the bodies' immune response to an infection causes injury to its own tissues and organs. The course and outcome of sepsis is highly heterogeneous and depends on complex host-pathogen interactions, the pathogen, and timing of diagnosis and effective treatment [1, 2]. Patients at risk for sepsis may benefit from personalized diagnostic assessment and treatment strategies. Multiple attempts have failed to develop classical biomarkers from e.g. serum to diagnose sepsis – also due to the heterogeneity of presentation. Digital biomarkers in sepsis may offer a different approach, as the collection of very large datasets allows to integrate time-series data of directly measured physiological parameters [3]. Within an integrative approach, digital biomarkers may be combined with -omics biomarkers (e.g. metabolomics, metagenomic, whole genome sequencing of bacteria, immune phenotyping) and form hybrid biomarkers with higher sensitivity and specificity. The use of novel machine-learning based algorithms to explore such datasets may help to better understand the data and discover patterns within the data linked to particular clinical phenotypes [2]. These algorithms may potentially allow to guide tailored personalized treatment strategies in sepsis. We aim to build a network for data-driven and -omics technology-based research to (i) recognize sepsis at an earlier stage and (ii) predict risk of mortality.

2. Methods

In the driver project funded by the Swiss Personalized Health Network (SPHN) and Personalized Health Related Technologies (PHRT), each University Hospital (Basel, Bern, Geneva, Lausanne and Zurich) and University of Bern and Zurich will provide data from critically ill patients hospitalized in intensive care units (ICUs).

The locally generated data is collected from various hospital information systems (IS) such as clinical and laboratory IS, devices such as ventilators and dialysis machines, ICU monitors, and treatment-related data, e.g. drug doses and transferred and stored in local clinical data warehouses (CDWH). In order to follow Sepsis 3.0 criteria [4], we regularly tag patient with suspected sepsis and collect information in the clinical IS. This will allow to compute Sepsis-3 criteria and compare data patterns to this international accepted definition of sepsis. The data is structured and interoperable between centres following SNOMED CT and LOINC ontologies. Data is then transferred in a resource description framework (RDF) format after encoding and encryption via the BioMedIT nodes to the ETH domain for further analysis. A shared data model will be used for machine-learning based analysis. The legal and governance framework is established using a Data Transfer and Use Agreement (DTUA) and Consortium Agreement (CA) [Figure 1].

The clinical outcomes of our study include: (i) prediction of sepsis with new markers in comparison to Sepsis-3 criteria and (ii) prediction of in-hospital mortality. There are two prospective observational trials conducted with these patients.

Study A includes every patient admitted to an ICU. Following specific inclusion/exclusion criteria, we include sepsis (cases) and non-sepsis (controls) upon entry of the ICU. Of all patients with an ICU admission also available pre/post-ICU data will be integrated into the data analysis. We will compare data patterns between cases and controls in regards of the previously defined outcomes.

Study B includes a subgroup of the patients from Study A. In all five hospitals a total of 300 patients with severe community acquired pneumonia (cases) and 100 patients with a severe systemic inflammation (controls) will be included. We will collect additional patient material such as serum, whole blood for DNA and RNA, respiratory and stool material, immune cells and bacterial isolates. These samples will be in-depth characterized using metabolomics, metagenomics, whole genome sequencing and immune phenotyping technologies. Digital and -omics data will then be merged and analysed to form hybrid biomarkers. Again, case and control patients will be compared in regards of the previously defined outcomes.

3. Results

For the digital biomarker project (Study A) we have obtained ethical approval to collect data from 15,000 ICU patients from participating centres over the next few years. In addition, a data transfer and use agreement as well as a consortium agreement have been generated. The legal process to allow data sharing was complex and involved a multiple round assessment and discussion of the legal framework with various stakeholders.

A list of clinical, physiological and laboratory variables, covering more than 500 attributes of interest was generated and linked to ontologies such as time points, application route and dosage of specific drugs, etc. Collection of data has started at local levels with a total of already several hundred patients from the participating ICUs. Within the next 6 months, we expect data from 3,000 patients to be collected.

Data transfer and exchange protocols are currently tested with all CDWH, BioMedIT, and ETH domain teams and continuously improved.

The second -omics biomarker project (Study B) has not yet started. The ethical proposal has been submitted and decision is pending. Study preparation are progressing at all centers. In regards of the sample management different biobank information management software (BIMS) systems have been established in the various centers.

4. Conclusions

Ethical and legal frameworks are critical in a data-driven large consortium and this bottleneck should not be underestimated. The legal discussions show a different momentum, content and motivation compared to research questions. This should be anticipated in such a project. A lead legal institution may be a good concept to provide legal advice, besides the availability of the DTUA and CA. The legal situation of large healthcare project is complex and requires a professional support. There is a clear benefit of regular meetings with all stakeholders for in-depth discussions and finding solutions for challenges. Once fully functional, the current framework will allow to collect and store data for research purposes across all Swiss University Hospitals ICUs – beyond sepsis.

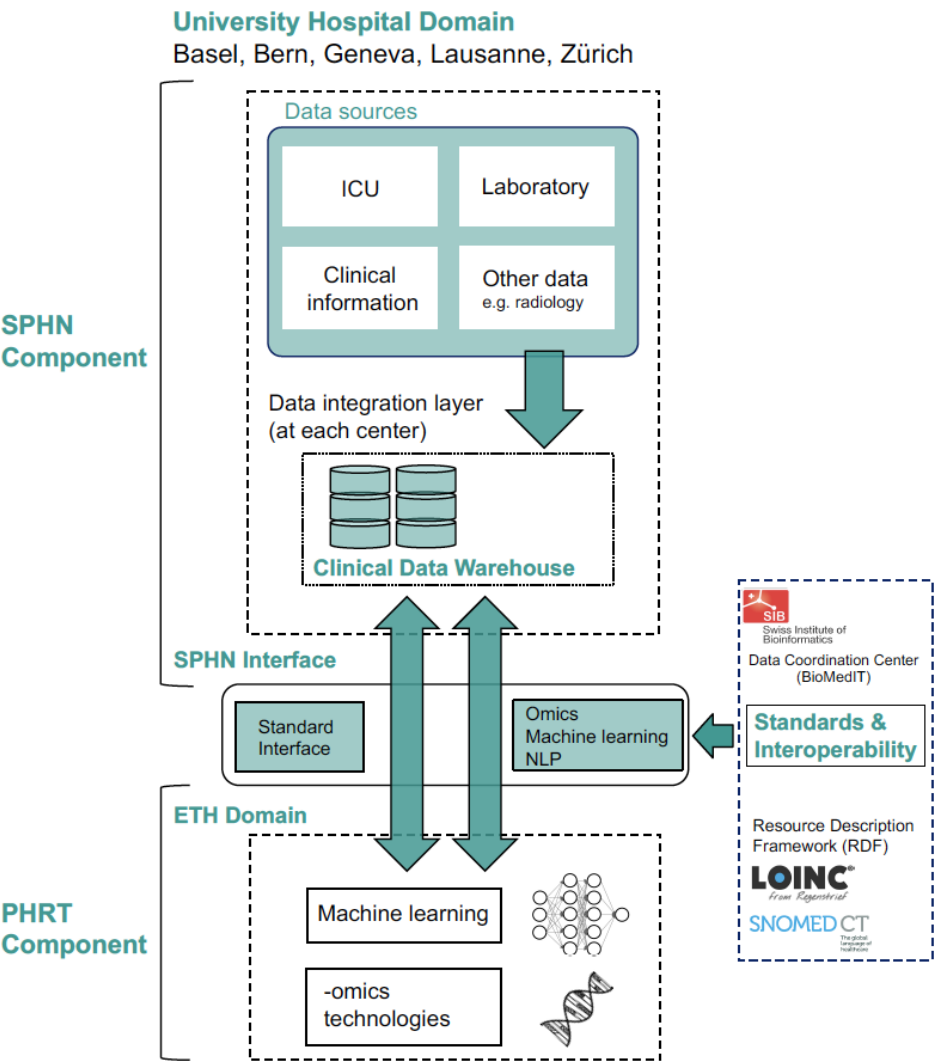

Figure 1. SPHN/PHRT framework for the Sepsis driver project. All centers locally collect data from different primary sources in clinical data warehouses. The is high interoperable and standardized following ontologies. The exchanged follows secured routes of BioMedIT to the ETH Domain for quality control and analysis. [1]

Abstract. In Switzerland by 2045, we expect 2.7 Mio citizens aged 65+ of whom 1.0 Mio. aged 80+. A priority and focus of personalized health research is therefore aging biology to extend healthy life expectancy. Novel molecular and imaging features will emerge as candidate targets for risk prediction and screening of chronic diseases. It is of utmost importance to test the clinical and public health utility of candidate biomarkers evolving from this research in citizen reference cohorts. We will build a Swiss Aging Citizen Reference (SACR), a testable and scalable reference cohort offering interoperable, searchable, and accessible data. 1000 participants from existing Swiss citizen cohorts will be combined and analyzed for DNA methylation and MRI brain imaging. SACR will serve as a testbed for clinical and public health utility of candidate biomarkers. As for a proof-of-concept study, we will conduct an agnostic search for structural and functional brain features associated with epigenetic aging acceleration to examine the potential of epigenetic age acceleration as the intermediate aging biomarker and to better understand the aging mechanism in brain.

Keywords. SPHN, personalized health, citizen reference, aging, DNA methylation, brain imaging

1. Introduction

The number of older citizens in Switzerland is growing. In 2045 pensioners aged 65+ are expected to account for over 2.7 million inhabitants, with over 1 million aged 80+. It is of strategic importance for the country from both, economic and public health perspectives, to maximize the healthy life expectancy of future elderly people.

Molecular and imaging biomarkers evolving from personalized health research depend on a healthy reference for utility testing. Citizen cohorts with prospectively sampled biomaterial are essential for investigating the reference distribution of exposome, risk prediction and screening biomarkers and their independent value in predicting morbidities. Among many indices and markers of biological aging, DNA methylation in blood has been demonstrated as a robust aging biomarker, with potential to interrogate molecular mechanism behind aging. DNA methylation-derived epigenetic

¹ Corresponding Author, E-mail: nicole.probst@swisstph.ch.

age acceleration was cross-sectionally associated with poorer cognitive performance (fluid intelligence), lower grip strength, poorer lung function, and with frailty.

Cognitive decline and neurological disorders are becoming one of the most significant socio-economic burdens of our aging society. One of the fundamental questions in human neuroscience is how molecular and cellular processes in the living brain drive cognitive changes over the lifespan. In recent decades the study of brain structure and function in health and disease has been greatly aided by the advent of magnetic resonance imaging (MRI) and started revealing how acute focal lesions and chronic neurodegeneration can lead to impaired cognition and disease states.

In this SPHN driver project we will build a Swiss Aging Citizen Reference (SACR) as a public health pillar for personalized health in Switzerland, where we implement brain imaging biobank into existing Swiss citizen cohorts to test the clinical and public health utility of candidate biomarkers including epigenetic age acceleration.

2. Methods

We build a scalable SACR infrastructure to integrate existing Swiss citizen cohorts, SAPALDIA, SKIPOGH, and CoLaus|PsyCoLaus, offering interoperable, searchable, and accessible data for researchers. The SACR population will continue to grow by integrating additional citizen cohorts in the future.

DNA methylome and MRI brain imaging data will be obtained for 1000 SACR citizens from the three cohorts. DNA methylome is already available in SAPALDIA and will be obtained for SKIPOGH and CoLaus|PsyCoLaus. MRI brain imaging has been conducted in CoLaus|PsyCoLaus and will be complemented for SAPALDIA and SKIPOGH. As for a proof-of-concept study, structural and functional features derived from quantitative MRI indicative for brain's myelin, iron and free tissue water content will be agnostically searched for association with epigenetic age acceleration.

3. Expected results

From the proof-of-concept study, we will identify brain microstructure features associated with epigenetic age acceleration, which is considered as an early biological aging marker, therefore we will provide evidence towards the validity of epigenetic age acceleration as intermediate aging biomarker. Further analyses on the brain imaging features towards aging phenotypes, e.g. cognitive function, will contribute to better understanding of brain aging, and potentially to its prediction at an early stage.

4. Public health impacts

As a result of this SPHN driver project, we will have a testable and scalable reference “SACR”. This will constitute the public health pillar for personalized health in Switzerland, offering interoperable, searchable, and accessible data for personalized health researchers. Archived biomaterial and data from SACR participants will be accessible for testing the clinical and public health utility of candidate biomarkers and exposome features in predicting biological age and age-related (multi-)morbidity.

Abstract. The BioMedIT project is funded by the Swiss government as an integral part of the Swiss Personalized Health Network (SPHN), aiming to provide researchers with access to a secure, powerful and versatile IT infrastructure for doing data-driven research on sensitive biomedical data while ensuring data privacy protection. The BioMedIT network gives researchers the ability to securely transfer, store, manage and process sensitive research data. The underlying BioMedIT nodes provide compute and storage capacity that can be used locally or through a federated environment. The network operates under a common Information Security Policy using state-of-the-art security techniques. It utilizes cloud computing, virtualization, compute accelerators (GPUs), big data storage as well as federation technologies to lower computational boundaries for researchers and to guarantee that sensitive data can be processed in a secure and lawful way. Building on existing expertise and research infrastructure at the partnering Swiss institutions, the BioMedIT network establishes a competitive Swiss private-cloud – a secure national infrastructure resource that can be used by researchers of Swiss universities, hospitals and other research institutions.

Keywords. Personalized health, SPHN, research infrastructure, scientific IT services, federated computation, sensitive data, confidential data, data privacy, data security, health-related data, interoperability, private-cloud, service virtualization

1. Introduction

The advent of digital transformation in health care has produced an exponential increase in the amount of information available for each patient. The use of this information in data-driven biomedical research has the potential to drive important changes in medicine [1]. In order to be able to leverage the potential of health-related data through biomedical research, data science and related research fields, data needs to be interoperable and available to researchers in various disciplines. In addition, strong capabilities in clinical bioinformatics and computational service infrastructure are required in order to enable the integration and interpretation of large and rich data sets. Furthermore, big data analyses and machine learning require vast amounts of data and accordingly high-performance IT infrastructures for computing and storage.

Given the sensitive nature of health-related information, data-driven personalized health research requires special IT infrastructures and services, blending the concepts of (i) security and compliance to protect the confidentiality of the data and the privacy of the research study participants; (ii) scalability and performance to be able to adapt to changing needs of users; and (iii) flexibility and ease of use to foster cutting-edge biomedical research. Security measures for Information and Communications Technology (ICT) systems are necessary to protect confidential information from unauthorized use, modification, loss or release². A few years ago, these requirements were not a major concern for academic computing facilities in Switzerland because those were predominantly tailored towards the handling of (insensitive) basic research data.

Another important requirement concerning the architecture of IT infrastructures for researchers working in multidisciplinary networks on big data sets in the biomedical field, is the possibility for controlled access to data sets across research teams from different institutions, also cross borders. In addition, in the context of nation-wide collaborative research projects, technical interoperability between different IT infrastructures should be granted in order to enable reproducibility of data analysis workflows executed at distributed locations [3].

To address the needs listed above, the BioMedIT project was funded by the Swiss federal government for the period of 2017-2020 within the framework of the Swiss Personalized Health Network Initiative (SPHN) [4] and in close collaboration with the strategic focus area Personalized Health and Related Technologies (PHRT) of the Swiss Federal Institutes of Technology (ETH) domain [5]. The aim of the project is to provide all researchers in Switzerland with access to a service infrastructure for collaborative analysis of confidential data without compromising data privacy. The intention is to create and maintain a national infrastructure resource that can jointly be used by all Swiss universities, research institutions, hospitals and other interested partners.

2. The BioMedIT Network: a National Secure Infrastructure Resource for Switzerland

The BioMedIT network builds on three scientific IT competence centers – the BioMedIT nodes – in different geographical locations: one in Basel (sciCORE, operated by the University of Basel), one in Lausanne (Core-IT, operated by the SIB Swiss Institute of

² Key elements of an effective ICT security system include (i) Monitoring and controlling access to confidential information; (ii) Safe transmission of data, and (iii) Secure storage and disposal of data [2].

Bioinformatics) and one in Zurich (SIS, operated by ETH Zurich). Over the past two years, all three nodes established secure compute and data platforms specialized on handling confidential research data that is subject to legal and ethical constraints. The computational service infrastructure is available to Swiss universities, research institutes, hospitals, service providers and other interested partners (*organizational clients*, see Section 2.4) that are not part of the BioMedIT network, to securely store, manage and process confidential research data. In addition, and specifically within the framework of the two Swiss national initiatives SPHN and PHRT, the BioMedIT network can be used for mono- and multi-site, individual and collaborative research projects (*project clients*, see Section 2.3). In fact, several innovative biomedical research projects [6] are already using a first version of the BioMedIT infrastructure.

2.1. Security Aspects of the BioMedIT Network

A common Information Security Policy [7] that applies to the entire BioMedIT network, defines the necessary organizational and technical measures to allow researchers to process sensitive data in a secure way³. This policy controls the way the confidentiality, integrity, and availability of information is handled, preventing misuse and malicious damage. In conventional high performance or high throughput systems available in scientific environments, the physical hardware and the respective software services are shared between all users. For data privacy and security reasons, BioMedIT takes a different approach: researchers involved in one particular project work completely isolated from any other project, meaning that all the data, software and resources belong exclusively to that project and there is no possibility to access it in any other way or from any other path. To this end, virtualization technologies are applied to establish private-cloud environments in which each scientific project is completely isolated from other projects with respect to data and compute resources. Access of authorized users to any project space requires two-factor authentication. Furthermore, users that are authorized to use the secure BioMedIT network can only access the infrastructure from within trusted IT environments (either from within Swiss university or university hospital networks or via VPN). Access to the Internet from the BioMedIT nodes is strictly controlled, limited to trusted and explicitly white-listed web resources.

The three BioMedIT nodes share a common security architecture to transfer, store, manage, analyze and share biomedical data while following the latest technical and legal standards required by Swiss legislation⁴ as well as internal regulations of the associated institutions. For project-related data transfer, an end-to-end encryption process from the data source through the BioMedIT network to the project space is set up, based on public-key cryptography. Special consideration is given to key management which is provided as a central service to users of the network.

Furthermore, the network follows the SPHN Ethical Framework for Responsible Data Processing in Personalized Health Research [11]. Importantly, before using the secure BioMedIT network, users are requested to follow a data security awareness training. BioMedIT offers the “Data Privacy and IT Security Training” as on-line

³ In general, sensitive data (as it is defined according to Swiss and international data protection legislation) is classified as “confidential” according to the SPHN Information Security Policy.

⁴ In particular, the Federal Act on Data Protection [8], the Human Research Act [9], the EU General Data Protection Regulation [10]

training [12] or class-room course hosted regularly in different cities in Switzerland. Finally, users must pass a mandatory on-line exam.

2.2. Technical Features of BioMedIT's ICT environment

The BioMedIT nodes provide a broad range of secure services to store, manage, process and share biomedical data. For example, multi-CPU (central processing unit) and multi-GPU (graphics processing unit) compute nodes are connected by fast internal networks to large and fast parallel file systems and state-of-the-art data management services. To date, the BioMedIT infrastructure features data storage capacity approaching in total 5 PB, support for data encryption, secure backup, private-cloud and high performance computing (HPC) leveraging more than 3000 CPU cores and 324 GPUs. State-of-the-art software for data science and specialized tools for data management are provisioned alongside with long-standing expertise in scientific IT support for research data management, bioinformatics, HPC and computational analysis.

2.3. Lowering Computational Barriers for Researchers (Project Clients)

The BioMedIT network provides a flexible ICT environment, and individual project spaces can be configured based on the researcher's computational and storage needs. This includes storage and compute capacity, up-to-date data analysis and modeling software packages, as well as backup and archiving solutions. The nodes can provide secure work environments for basic exploratory data analysis but can also scale up to cover high performance and high throughput needs such as large-scale machine learning.

The BioMedIT portal, a central service of the network operated by the SPHN Data Coordination Center of SIB's Personalized Health Informatics Group, provides a single access point to the BioMedIT nodes and associated resources, simplifying access control for the researchers. Depending on the use-case, the BioMedIT network can be accessed by command-line or by web-based remote-desktop technology.

Standardized ways for secure data transfer from partner institutions, such as the five Swiss University Hospitals, the PHRT data centers and other data providers are currently being established and will be available to all projects relying on data from any of these providers.

The BioMedIT network aims to enable interoperable workflow execution, providing a way for researchers to work seamlessly across the nodes. Containerization of data workflows using Open Container Initiative (OCI) standards [13] are playing an important role for this and will at the same time improve reproducibility of results obtained by these workflows. The ultimate goal of BioMedIT is to provide a data-aware federated analysis platform where researchers can work with distributed data. This approach is especially valuable for confidential data or large data sets, which cannot easily be shared.

2.4. Outsourcing Sensitive Research Data Operation to BioMedIT (Institutional Clients)

While the focus of the BioMedIT network is to support national research projects in the SPHN and PHRT programs, the BioMedIT nodes are creating a unique data and computing environment that will be useful and potentially required for research activities outside of these programs. Clinical institutions scaling up their data processing in preparation of clinical research projects or clinical decision support strategies,

consortium projects with public and private partners, or novel ways to run clinical trials, which create large amounts of trial data and require good clinical practice (GCP) compliant data management, are examples for it. The BioMedIT nodes are offering a safe environment for these types of activities and are working on enhancing their platforms for future needs. By linking to the BioMedIT network, Swiss research institutions and hospitals can hence benefit from a trusted research IT infrastructure without the need to (re)develop costly *in-house* infrastructures and know-how.

3. Conclusion

BioMedIT provides data resources and a network of secure data nodes for doing data-driven research on sensitive (confidential) biomedical data. It lowers computational barriers by provisioning an efficient solution for cross-institutional analysis of sensitive data, and is therefore unique in Switzerland. The technical solution is comparable to related activities within ELIXIR in various European countries [14]. However, BioMedIT operates within a national network of health-care providers, infrastructure and research support groups, research projects as well as citizens, and therefore has a great potential to become a platform of reference for health data exchange and analysis. A first version of the BioMedIT network is established and already used by SPHN and PHRT projects and pilot collaborations with Swiss university hospitals. These projects help shaping new versions of the BioMedIT infrastructure to make it even more useful, efficient and secure for current and future biomedical research applications.

A Digital Service Logistics Information System for Emergency Department Care Coordination - Professionals' Experiences

Laura-Maria PELTONEN^{a,1}, Armi KULOHEIMO^a, Kristiina JUNTILA^a, Sanna SALANTERÄ^a

^a*Department of Nursing Science, University of Turku, Turku, Finland*

Abstract. The aim was to describe nurses' and physicians' perceptions of a digital service logistics information system from an operative management perspective in emergency departments (EDs). A total of 24 professionals were interviewed. Based on the results the information systems support operative management of EDs but the professionals desire more detailed information about patients and staff to support situational awareness in the operative management of these units.

Keywords. Emergency Department, Information System, Care Coordination

1. Introduction

Although information management in health care today is widely digitalized and electronic health records have received attention, less is known about information systems developed for operational management. Timely access to important information is essential when managing the day-to-day operations of emergency departments (EDs) in hospitals as decisions typically must be made without delay [1].

This study focuses on a service logistics information system (Columna Clinical Care Logistics®) that displays information about patients, staff and care processes for the professionals. It is available in hospitals on screens, personal computers and mobile devices. The system aims to support easy access to important information for multiprofessional needs. The aim of this study was to describe nurses' and physicians' perceptions about this information system from an operative manager's perspective in an ED.

2. Methods

The study had a cross-sectional design. Data were collected in three EDs, including two emergency departments and one emergency inpatient ward in two central hospitals in Finland. A total of 24 professionals, including 7 physicians and 17 nurses, who were in charge of coordinating care, participated in the study. Data were collected through interviews with two open ended questions: 1) What do you think is good about the

¹ Corresponding Author, E-mail: laura-maria.peltonen@utu.fi.

service logistics system? and 2) what could be improved regarding the service logistics system? Data were collected in the autumn of 2018 and spring of 2018. Data were analysed using thematic content analysis [2].

3. Results

The mean age of the respondents was 42.4 years (SD 10.2) and their mean work experience was 17.2 years (SD 11.7). Three respondents worked only at office hours, three worked only beyond office hours and eighteen worked both during office hours and beyond. Issues regarding the information system were divided into three main themes.

- Support for care coordination: The system provides multidisciplinary task management support and a quick overview of patients, staff and processes, but the complexity of care needs and staff skills was not shown in sufficient detail.
- System implementation and usage: Personal traits and the information management culture influenced system usage, and professionals used the system to a different extent when measured at one year after implementation.
- Information exchange: A lack of information exchange with other systems limited the possible benefits in communication between care providers.

4. Discussion

The digital service logistics information systems support operative management of EDs. However, professionals desire more detailed information about patients and staff for situational awareness. Artificial intelligence could be used to support this task. Further, it takes a long time to learn how to use such an information system as it changes the professionals' work. Hence, the need of a long follow-up period needs to be considered when measuring the impact of such systems to ensure that all users use the system in the way expected. In conclusion, digital service logistics information systems can support professionals' situational awareness in EDs, but they should be developed based on evidence of information needs. Reliable use requires that all users use the system to its full potential.

A Matlab Tool for Organizing and Analyzing NHANES Data

Simon Lebech CICHOSZ¹, Morten Hasselstrøm JENSEN^{1,2},
Thomas Kronborg LARSEN¹, Ole HEJLESEN¹

¹*Department of Health Science and Technology, Aalborg University, Denmark*

²*Steno Diabetes Center North Denmark, Aalborg University Hospital, Denmark*

Abstract: Automation of organizing and analyzing NHANES data can provide easier access to data and potentially reducing risk of introducing bias. This study investigates the potential for developing a software for this purpose. MATLAB R2016b was used for transforming and analyzing data from the NHANES. The software was tested successful by analyzing the association between smoking and glucose metabolism in the general population.

1. Introduction

The National Health and Nutrition Examination Survey (NHANES) (1) is a large, stratified, multistage survey conducted by the Centers for Disease Control (CDC) which collects health data on the US population. Data are made publicly available in two-year cycles and the data are categorized into six main areas; dietary, demographics, examination, laboratory, questionnaire, and limited access data.

However, there is an absence of reproducible software and methods that transforms the data from its published online format into an analytic dataset. Even though the NHANES data are publicly available, actually analyzing the data requires a non-trivial amount of background information, data processing and linking. This preprocessing is prone to introducing bias into the data and requires considerable time and resources. We sought to investigate the potential for developing a software for simplifying this process and as an example applying the tool for analyzing the association between smoking and glucose metabolism in the general population.

2. Methods

We developed in MATLAB R2016b a two-level tool. Based on the desired NHANES year-cycles and data variables of interest the first level of the tool will download the relevant data from the public repositories and organize the files locally. The data files are published as a .xpt (SAS XPORT) format, therefore the files are subsequently imported and converted to tables in MATLAB which are then linked based on year-cycle and type of variable. Based on the merged data the second level of the tool is able to analyze data (using an chosen statistical method) and produce tables with patients' characteristics and effect estimates of independent variables in an unadjusted or adjusted analysis. In our study of smoking and glucose metabolism, several years of NHANES (2005-2014) and data types were utilized. From demographics, gender and age data were

collected; from laboratory, fasting glucose and oral glucose tolerance test (OGTT) results were collected; from examination, blood pressure and body mass index (BMI) were collected; and from questionnaire, data on smoking and alcohol habits were collected. The effect of current smoking was assessed in an unadjusted and an adjusted analysis, taking the mentioned covariates into account (gender, age, alcohol usage, BMI).

3. Results

The MATLAB tool was successful in organizing and analyzing data from several year-cycles of NHANES. A total of 12460 participants was identified as currently smoking (n=2575), ex-smokers (n=3032), and never smoking (n=6853). Currently smoking was in the unadjusted analysis associated with higher fasting glucose (effect 3.46 mg/dL, SE:0.72, $p<0.001$). In the adjusted analysis smoking was associated only with lower OGTT (effect -3.94 mg/dL, SE: 1.44, $p=0.01$)

4. Discussion and conclusion

Automation of organizing and analyzing NHANES data can provide easier access to data and potentially reducing risk of introducing bias. The tool was successfully applied on data from several year-cycles. The test results showed a surprisingly negative association between smoking and OGTT. This association needs to be investigated in more detail.

A Path to Inclusion: Design and Prototype of Transgender Identity in an Electronic Health Record

Melanie CASSARINO^{1a}, Eunice CORREA^a, Sebastián MINOLETTI^a, Ignacio JAUREGUI^a, María Florencia GRANDE RATTI^a, Carlos OTERO^a, Daniel LUNA^a

^a*Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*

Abstract. With the purpose of reducing discrimination on gender, the Department of Health Informatics of the Hospital Italiano de Buenos Aires (HIBA) developed changes in its Patient Master Index to register chosen name and self-perceived gender identity. To improve the visualization of information related to the identity of each person to provide comprehensive quality care, it was decided to modify the impact of this information on the EHR. For this, prototypes were developed with changes in the patient identification module and then user-tests were carried out.

Keywords. Transgender, Electronic Health Records, Identification, Gender.

1. Introduction

Gender identity is the internal and individual experience of gender as each person feels it, which may or may not correspond to the sex assigned at the time of birth. This may involve the change of the appearance or body function through pharmacological agents, surgery or other, when it is freely chosen. It also includes other gender expressions, such as dress, speech and manners.

Since 2018, the **self-perceived gender** of the patient and their **chosen name** are included in the registration system [2]. In order to improve the visualization of information related to the identity of each patient to provide comprehensive quality care, it was decided to incorporate this information on the EHR. For this, prototypes were developed with changes in the patient identification module and then user-tests were carried out. The aim of this study is to describe the user-centered design process, used to visualize the identification of transgender patients within the Electronic Health Record.

2. Methods

Inquiries and usability tests were carried out with HIBA health professionals. Sample selection was for convenience. Users had to present the following inclusion criteria: be a health professional (regardless of training level), have used the EHR for at least 6 months in in- and outpatient settings, without knowledge of the Transgender project.

¹ Melanie Cassarino, E-mail: melanie.cassarino@hospitalitaliano.org.ar

2.1 Design

Stage 1: Situational diagnostic: Includes reviewing the literature using PUBMED. The articles were manually reviewed and a selection was made of those that mentioned the identification of the different identities in the EHR. Then, the current legislation in our country was evaluated to include the regulatory framework.

Stage 2: Design and evaluation: Prototype Design: From the bibliography found, the Gender Identity Law [1] and the iconography, different prototypes were designed to cover the different use cases. They consisted of a capture of the summary module of the Electronic Health Record. On the sidebar, where the affiliate data is found, the icon was linked with the chosen name, followed by the initials of the legal name. Likewise, the last name, the chosen name, the legal name, the gender, a hyperlink to the gender law and the biological sex were included in the "More data" menu.

Stage 3: User tests: A test round was carried out with five different users. Interfaces of the EHR with the iconographic incorporation were evaluated. A clinical case about a transgender patient with a chosen name, but without a change of birth ID, was conducted. Users were shown a mock up with the visualization of the case data. They were asked to interpret the patient from data, describe what they saw, decide the gender of the patient. Each professional was asked about whether he detected any change in the display of the patient's identity information, what the selected icon meant and what he thought the letters in brackets were referring to. This test was carried out in the workspace of each professional. After each test, reports were made with the findings per user.

3. Results

Prototype testing: All focused their answers on the patient's **clinical** data, that is, about the diagnosis, the reason for consultation and medical history. The majority of the professionals who participated in the test interpreted without hesitation that the patient in the case was "male". Only two users doubted the gender because it presented interconsultation with gynecology. This was expressed in phrases such as "*I doubt because in records it says that it consults for infection of the cervix, is he transgender?*" and "*I think it is male because his name is Mariano but here in records they put it that it has a cervix and also they made him an interconsultation with gynecology. Did they make a mistake?*"

All professionals agreed that they usually infer the patient's sex through their name. The majority could recognize, after careful observation, that the icon represented in the prototype corresponded to the "transgender" identity. In turn, all users agreed that the letters in parentheses were new information in the EHR, but could not infer their meaning. These users expressed "*I don't know, but now that I see that it is transgender I think that maybe is related to its old name*". In conclusion, we believe that it is essential to accompany the adapting process to the information system with instances of awareness, education and training of both administrative and health staff. In this sense, it is vital that all employees of the institution understand the importance of respecting each person's perception of themselves and how they want to be identified. Respecting and enforcing each other's gender identity allows us to live in a society with less discrimination and more understanding of others.

A Recommender System Based on Cohorts' Similarity

Abstract. Aiming to better understand the genetic and environmental associations of Alzheimer's disease, many clinical trials and scientific studies have been conducted. However, these studies are often based on a small number of participants. To address this limitation, there is an increasing demand of multi-cohorts studies, which can provide higher statistical power and clinical evidence. However, this data integration implies dealing with the diversity of cohorts structures and the wide variability of concepts. Moreover, discovering similar cohorts to extend a running study is typically a demanding task. In this paper, we present a recommendation system to allow finding similar cohorts based on profile interests. The method uses collaborative filtering mixed with context-based retrieval techniques to find relevant cohorts on scientific literature about Alzheimer's diseases. The method was validated in a set of 62 cohorts.

Keywords. Alzheimer cohorts, Cohort catalogue, Recommendation systems

1. Introduction

There is a need for discovering new biomarkers to diagnose Alzheimer's disease in the predementia stage to predict the rate of decline [1]. Therefore, several institutions increased the efforts in collecting Alzheimer's patients' data, as well as to build a harmonised structure to store these cohorts.

In the EMIF project¹, we have developed a platform to collect and publish metadata about EHR databases and disease specific cohorts [2]. The EMIF Catalogue includes several communities, one of them dedicated to the study of Alzheimer's disease. In this centralised platform, data sets are classified through a set of general characteristics, which allow the identification of similar patterns across the collection. However, the manual analysis of these similarities is time consuming and hard to perform.

In this paper, we propose a methodology that, based on previous knowledge gathered from user's preferences and user's data sets, is able to suggest similar cohorts and related scientific publications. The method uses collaborative filtering and context-based retrieval techniques, taking as inputs the cohorts' metadata in a predefined ontology, its concepts and relationships.

¹<http://www.emif.eu>

2. Methods and Materials

The EMIF Catalogue is a web platform for biomedical data sharing, where data custodians can publish information about their data sets [2]. This information is mainly statistical information and aggregated databases' metadata. In the platform, researchers can search for databases of interest and request access to the raw data, data subsets, or ask to perform certain research questions.

Most of the research studies do not follow a standard structure or format, because they are built with a specific purpose, with inclusion/exclusion criteria. To allow the reproducibility of research questions in different cohorts, our strategy was the adoption of a taxonomy implemented using an ontology with the recorded variables and also the values (columns and rows). This method allows comparing multiple cohorts, i.e., all the variables will be mapped into ontology classes, and this ontology supports relationships between concepts, following a hierarchical tree with root entities that represent core categories that are being followed (i.e. Patient Demographic Data, Neuropsychiatry, Laboratory Results, etc.). Moreover, it is also possible to create constraints in the cohort scope, and it is flexible enough to extend or create new variables. The ontology management is maintained by community using a common RDF (Resource Description Framework) specification.

3. Results and Conclusions

We proposed a recommendation system that combines two techniques. The collaborative filtering can detect similar users and provide the recommendation based on the analysis when the cohorts structure of the users interest are too disperse. On the other hand, the context-based retrieval can predict suggestions when the user is more singular, by relying only in the cohorts' concepts. We applied evaluation metrics to each individual approach and then combining both strategies. The methodology was integrated in the EMIF Catalogue platform, using the statistical data collected from the Alzheimer's community. This group gathered metadata information from 62 cohorts, representing in total 661 concepts, which have also been indexed through our system. This community has more that 500 registered users, allowing a first test-bed to apply our methodology.

A Smart Mapping Editor for Standardised Data Transformation

Hannes ULRICH^{1a}, Sebastian GERMER^c, Ann-Kristin KOCK-SCHOPPENHAUER^a,
Jori KERN^b, Martin LABLANS^b and Josef INGENERF^{a,c}

^a *IT Center for Clinical Research, University of Lübeck, Germany*

^b *Federated Information Systems, German Cancer Research Center, Heidelberg, Germany*

^c *Institute of Medical Informatics, University of Lübeck, Germany*

Abstract. The integration of heterogeneous healthcare data sources is a necessary process to enable the secondary use valuable information in clinical research. Data integration is time-consuming for data stewards. The transformation using predefined rules for data harmonization can reduce the time-consuming and error-prone work and ease the data integration at various sites. In our study, we examined various script(ing) languages to find the most suitable candidate for definition of transformation rules and implement a smart editor which supports the data stewards in selecting rules reusing them. Thereby, it also provides an automatic and seamless documentation to strengthen the reliability of the defined transformation rules.

Keywords. Health Information Interoperability, Data Warehousing, HL7 FHIR

1. Introduction

The increasing digitalization of the healthcare sector produces a variety of new data sources which should be integrated to exchange data and therefore enable secondary use in clinical research [1]. But often, the origin and prior processing steps are not well documented, impeding the ability to reliably determine the data origin and thus hampering reproducible research [2]. Therefore, the data origin must be reliable. Data integration and therefore data transformation needs suitable tools to transform information with seamless documentation. Data stewards need to examine both input and output formats and define conversion rules and confirm the performed transformation. A broad variety of open source integration tools is available to extract, load and transform [3]. However, they share the same lack of exchangeability: the transformations are encoded locally in a proprietary representation. Healthcare data provider and integration centres facing the same integration problem, could benefit from exchanging these transformation schemes [4].

2. Methods

A standardized data format and a commonly used transformation language are needed to promote the exchange of transformation rules. HL7 FHIR is a suitable

¹ Corresponding author: E-mail: hannes.ulrich@itcr.uni-luebeck.de

communication standard, which defines 143 interoperable resources including three suitable for transformation: *ConceptMap*, *StructureMap*, and *Provenance*. JavaScript is one of the internet core technologies and due to the code execution in the browser on every common environment applicable.

3. Results

We took the requirements into account and implemented an editor service. The development focused a modular structure with standardized HL7 FHIR input and outputs formats, assistance for the data steward and reproducibility of the created mappings. The ConceptMap is uploaded manually or received from a FHIR server. The content is visualized with additional details about the source and target data element [5]. The editor provides syntax highlighting for various script languages and live checking to minimize errors. The data steward can define the transformation in JavaScript and use sample data to validate the mapping in real-time. A proposal function is based on previously stored transformation rules and locally-sensitive hashing function [6]. OpenID Connect was used to obtain the user information for the Provenance resource. The editor exports the resulted mapping as a FHIR bundle including a StructureMap, a Provenance and the corresponding steward in a Practitioner resource. The source code of the editor is available on <https://github.com/itcr-uni-luebeck/>.

4. Discussion

The editor focuses on standardized approach to exchange defines rules to minimize the time-consuming integration task. Our approach uses FHIR resources to promote this exchangeability and enables a *plug and play* for data integration to expedite the process. The choice of JavaScript as the transformation language ensures system-independent use since every common browser is capable of executing the rules. Nevertheless, the editor is implemented modular and language-agnostic, e.g., the use of Python is possible. In conclusion; Our study aims at closing the documentation gap for metadata-driven data integration by providing a supportive editor for the better reproducibility.

Accessible Rates to Health Information on the Internet in Elderlies Increased Among Fifteen Years

Takeo SHIBATA^{a,1}, Akemi KUNIMATSU^b, Chika HIRAGA^b, and Yoko SHIMIZU^c

^a*Department of health management, Tokai University, Japan*

^b*Division of Health and Welfare, Yuzawa Town, Japan*

^c*Graduate School of Nursing, Tokyo Women's Medical University, Japan*

Abstract. Yuzawa Town, located in the Niigata prefecture of Japan, is famous for its hot springs. A citizen-centered health promotion program, Yuzawa family health plan, was initiated in 2002. It has been held for seventeen years. We evaluated changes their accessible rates to health information on the internet between 2002 and 2017 in elderlies. 431 and 435 questionnaires were corrected from elderly people at least 65 years old at 2002 and 2017. The accessible rates to health information on the internet in elderlies increased ($p < 0.001$). Profiles of accessible elderlies to health information on the internet were shown. Son and daughter might give them health information. Elderlies having any health concern or anxiety might be afraid to take health information. Accessible elderlies to health information were able to resolve suffering and breach risks by oneself.

Keywords. health promotion, health information, elderly

1. Introduction

Yuzawa Town, located in the Niigata prefecture of Japan, is famous for its hot springs. The number of citizens is about eight thousands. The population is decreasing, because Yuzawa town is one of fast aging towns in Japan. A citizen-centered health promotion program, Yuzawa family health plan, was initiated in 2002. It has been held for seventeen years. Questionnaires were collected every five years. We evaluated changes their accessible to health information on the internet between 2002 and 2017 in elderlies. We evaluated the profiles for accessible to health information on the internet at 2017.

2. Methods

431 questionnaires were corrected from elderly people at least 65 years old at 2002, and 435 questionnaires were corrected at 2017. Chi-square test was used to compare the rate of accessible health information on the internet. Chi-square test was also used to evaluate related profiles with accessible to health information on the internet at 2017 in elderlies.

¹ Corresponding Author

Evaluated profiles were living alone, living with marriage partner, living with son or daughter, living with grandchildren, living with brother or sister, health consciousness, attention to health, health concern, awakening in a morning, clockwork life, fitness habits, smoking, taking alcohol, anxiety, loneliness, consultation, resolve suffering, economic problem, handle stress, taking a rest, risk breaching, communication, life satisfaction, talking with family, job at home, intercommunion with friends, greeting with neighbors, relationship with neighbors, relationship with babies, relationship with elementary school children, relationship with junior high school students, relationship with high school students, relationship with young adults, relationship with middle aged adults, and relationship with elderlies.

3. Results

Accessible rates to health information on the internet in elderlies increased from 4.5% at 2002 to 13.1% at 2017 ($p<0.001$).

Living alone ($p<0.01$), living with marriage partner ($p<0.01$), taking alcohol ($p<0.05$), resolve suffering ($p<0.05$), risk breaching ($p<0.05$), talking with family ($p<0.01$), and relationship with middle aged adults ($p<0.01$) increased the accessible rate to health information on the internet at 2017. Living with son or daughter ($p<0.01$), health concern ($p<0.05$), anxiety ($p<0.05$), consultation ($p<0.01$), and relationships with neighbors ($p<0.05$) decreased it.

4. Conclusion

Accessible rates to health information on the internet in elderlies increased about three times between 2002 and 2017. Profiles of accessible elderlies to health information on the internet were shown. Though living alone or living with marriage partner increased accessible rates to health information, living with son or daughter decreased it. Son and daughter might give them health information. Elderlies having any health concern or anxiety might be afraid to take health information. Accessible elderlies to health information were able to resolve suffering and breach risks by oneself.

Addressing Ethics in the CrowdHEALTH RDI Project Concerned with Large Amounts of Data to Support Health Policies

Lydia MONTANDON^{a,1}

^aResearch & Innovation, Atos Spain, Spain

Abstract. CrowdHEALTH is a R&D project involving high volumes of health-related data. Although partners have been complying with all regulatory and ethical issues according to their context in different EU countries, ethical aspects related to the adoption of the project results and possible impact on individuals and populations were not in the project agenda from the outset. Inspired by an increasing number of initiatives in the EU concerned with aspects related to ethics in research and innovation, future plans consider investigating the level of awareness of all stakeholders involved in the project about the potential implications of their actions in terms of ethical acceptance of project outcomes.

Keywords. Ethics, Ethical Issues, Responsible Innovation, RRI

1. Introduction

CrowdHEALTH is an EU research project that intends to collect and aggregate high volumes health-related heterogeneous data from multiple sources with the aim of supporting policy making decisions. A Policy Development Tool proposes an interface that allows policy makers to interact with data and key performance indicators to create visual representations that support the elaboration or evaluation of Health policies.

At project start, mainly ethical issues that may affect the research and the testing of developed results in real cases pilots were considered. In the context of CrowdHEALTH, ethical issues were principally centered on privacy and data protection and children and patients' involvement.

2. Method

The project collected information related to ethical requirements from partners that had to run pilots in their organizations. A structured template with hints for its fulfillment was provided to gather consistent data from all use cases. Contributions were integrated, extracting general procedures that applied to all pilots and describing the procedures specific to each pilot.

¹ Corresponding Author, E-mail: lydia.montandon@atos.net.

3. Results

The compiled document showed that all measures to ensure that the project complied with ethical principles and relevant national and EU legislation had been taken.

4. Discussion

However, considering CrowdHEALTH's intention is to facilitate the access and analysis of large amounts of data for policy – and maybe intervention in the future – that may have an impact on whole populations, potential ethical implications go beyond mere research ethics. The question arises whether the project is dealing with all ethical aspects in a proper way. The project faces ethical challenges related to subjecting individuals and populations to policies and interventions based on non-transparent data sources, processing and analyses. Although CrowdHEALTH is developing components to clean data and ensure quality and reliability, it is not fully clear who will be accountable for the quality of the data input, or the algorithms applied.

Inspired on the one hand by recent concerns and interest in the challenges that ethical aspects present when using technologies related to Big Data and Artificial Intelligence, where transparency and accountability are treated as key issues and, on the other hand by the EU's Responsible Research and Innovation (RRI) approach, implying that research in Europe needs to understand, anticipate, and address ethical, legal and social aspects, the project started wondering if all experts involved in the project were aware and applying methods to ensure that the results of the project are desirable and anticipate risks. We therefore started to shift our attention towards what could be done to anticipate effects related to ethical issues that would impact the adoption of the project outcomes.

5. Conclusive Remarks

It becomes evident that the project needs to investigate more if there is awareness within the team and if an individual questioning of choices and actions would be enough to ensure that project consortium culture is aligned with the EU RRI approach.

To obtain insight about all stakeholders involved in the project (researchers, designers, developers, etc.) awareness on ethical issues in their daily work, a survey is being launched, including a few demographic questions, to allow clustering per profile.

The objective is to reach directly individual experts along the research and innovation value chain, and understand how familiar they are with ethical aspects, such as transparency, accountability, social values, etc. and if this may result as a better understanding of ethical implication of the project outcomes on society.

Acknowledgements. The CrowdHEALTH project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 727560.

Advanced Machine Learning in Prediction of Second Primary Cancer in Colorectal Cancer

Chi-Chang CHANG^a, Ying-Chen CHEN^a

^a *Department of Medical Informatics, Chung Shan Medical University & IT Office, Chung Shan Medical University Hospital, Taichung, Taiwan*

Abstract. Colorectal cancer (CRC) ranked third among most commonly diagnosed cancers worldwide. The onset of second primary cancer (SPC) is an important indicator in treating CRC. We tried to use the advanced machine learning method in order to find the factors of SPC. Patients with CRC from three medical centers were identified from cancer registries in Taiwan. The classifier of A Library for Support Vector Machines (LIBSVM) and Reduced Error Pruning Tree (REPTree) were applied to analyze the relationship of clinical features with category by constructing the optimized model of every classified issue. Machine learning can be used to rank the factor affecting the secondary primary malignancy. In the clinical practice, physician should be aware the possibility of cancer recurrence and routine checkups for early second primary malignancy detection is recommended. The accuracy rate of the may need more big data. The machine learning method is feasible in detecting/predicting potential second primary cancer in the future.

Keywords. Colorectal Cancer (CRC), Second Primary Cancer (SPC), Machine Learning method.

1. Introduction

Colorectal cancer (CRC) is the third most common cancer in the world and the fourth most common cause of death overall [1]. It is also the most common type of cancer in Taiwan, the incidence of CRC is approximately 16%. Early detection of second primary cancers is essential to improve health outcomes of cancer patients. Therefore, a valid and reliable method/tool to help detecting the SPC is necessary.

2. Methods

Our study identified data associated with three medical centers from the cancer registry database (Taiwan). We used the ICD number C18–C20 to select the CRC patients. The colorectal cancer was all diagnosed from 2004 to 2012 and the age was 18 years old and above. A total of 4299 patients with primary colorectal cancer were enrolled. Of those, 541 samples had primary colorectal cancer plus second primary malignancies. In this study, we used the correlation analysis to examine the following 20 factors associated with colorectal cancer: patient age, primary site, histology, behavior code, differentiation, tumor size, pathologic stage, surgical margins, surgical procedure,

radiation therapy, pre-operative radiation therapy, regional body order, highest dose, maximum number of times, lowest dose, lower number of times, body mass index (BMI), smoking, areca and drink. We use LIBSVM (A Library for Support Vector Machines)[2] with the radial basis function (RBF) kernel to construct predictive models and optimize the C and γ parameters of each model. *REPTree Reduced Error Pruning Tree (REPTree)* uses the regression tree logic and creates multiple trees in different iterations. The predictive ability of each system was evaluated using accuracy (Acc), sensitivity (Sn), specificity (Sp), and the Matthews correlation coefficient (MCC).

3. Results

By LIBSVM implementation, the model building employed 8 features, which includes behavior code, differentiation, regional body order, patient age, areca, surgery, radiation therapy and lowest dose, could achieve the equivalent performance outcome with the model using all features in the analysis. Applying the REPTree algorithm, we found that the decision tree employed three features of patient age, differentiation and organizational patterns have better accuracy of MCC in 0.294 and Sn in 0.706 than original model by parameters optimization. From the decision tree architecture, we discovered the value of differentiation > 9.5 was classified as SPM, when value of differentiation < 9.5 , the organizational patterns and patient age were as the leaf node to classify the SPM and NSPM.

4. Discussion

Our study has explored risk factors for predicting second primary malignancy and discovered the top four important features were pStage, surgical margins, smoking and drinking. In addition, we found that the REPTree algorithm used only the three features (patient age, organizational patterns and differentiation) to optimize the parameters of REPTree model to improve performance. With machine learning program, we have developed a feasible and a robust method to identify four important factors: pStage, surgical margin, smoking and drinking contributing to the second primary cancer and recurrence in colorectal cancer. Mechanical learning can be used as an effective medical decision-making tool to assist physicians to establish a prognosis and improve their diagnostic accuracy. We strongly recommend clinicians to consider using mechanical learning method in diagnosing and treating cancer patients to provide high quality care.

Agent-Based Modeling and Simulation of Care Delivery for Patients with Thrombotic and Bleeding Disorders

Noemi GIORDANO^a, Samanta ROSATI^a, Federica VALERI^b, Alessandra BORCHIELLINI^b and Gabriella BALESTRA^{a,1}

^a*Department of Electronics and Telecommunications, Politecnico di Torino, Italy*

^b*Oncologic Department, Città della Salute e della Scienza di Torino, Torino, Italy*

Abstract. The quality of patients care delivery is thought to be strongly affected by the physicians' workload. In this study we present an Agent-Based model of the processes during a typical working day. We simulated the current scenario and a possible scenario concerning the introduction of a second ambulatory as a potential improvement in the center organization. Our results validated the reliability of the model and showed that the introduction of a second ambulatory averagely reduces the daily physician' workload.

Keywords. ABM, simulation, process modelling, clinical process, NetLogo.

1. Introduction

It is nowadays well known that the delivery of high-quality healthcare services to patients and the resulting clinical outcomes are dependent on the workload of the clinical staff. Physician's workload higher than normal and consequent stress were proven to negatively impact on clinical outcome and on the quality of care [1]. Computational modelling and simulation is a unique tool to get a deeper insight in complex systems' behavior and to predict the effect of changes [2]. The diffusion of Agent-Based Modelling (ABM) strongly increased across the latest decades to face the growing complexity of the world [2]. The aim of this work is to present an ABM of the care processes for patients with thrombotic and bleeding disorders with different scenarios and their effects on the physician workload. The study was conducted at the "Malattie Trombotiche ed Emorragiche" center of a Turin hospital.

2. Materials and methods

In a previous work [3], we described the process involved and performed data collection. Two Process Modelling tools, namely Synopsis diagrams and Swim lane activity diagrams, were used to analyze all clinical processes carried out by the two

¹ Corresponding Author: Gabriella Balestra, E-mail: gabriella.balestra@polito.it.

physicians of the center during a typical working day. The results were used to perform the ABM modeling and simulation. Among available ABM software and tools, we chose NetLogo 6.1.0 platform¹ for its simplicity in use, high scalability and high computational modelling strength.

In our model, we defined three types of agents: 1) “**Physician**”: specialists of the center; 2) “**Ambulatory patient**”: patients with scheduled ambulatory visit; 3) “**Internal advice patient**”: patients needing internal advice. Agents correspond to the actors previously identified as involved in clinical processes [3]. All agents moved and performed the activities in the simulation environment that was defined accordingly to the scaled map of real hospital. The model rules were defined by implementing the processes as previously modelled [3]. The simulation was based on several parameters statistically defined based on the collected data [3]. First, a simulation of an average typical day in the present situation was carried out to validate the reliability of the model. Then, since the ambulatory care absorbed the highest percentage of the workload, a new scenario was simulated to evaluate the effect of the availability of a second ambulatory room. Two different situations were modelled: (a) the second room was used only when ambulatory visits were performed both in the morning and in the afternoon; (b) the additional ambulatory was used in parallel with the first one.

3. Results and Conclusions

The results of the simulations are compared with the collected data. The overall physicians’ workload (expressed in minutes) was 557 ± 74 for the current scenario, 561 ± 76 for the new scenario (a), and 555 ± 58 for the new scenario (b). Comparing the collected data (566 ± 135 minutes) with those obtained from the simulation of current scenario it can be noticed that the results are consistent demonstrating the accuracy reliability of the developed model. Moreover, it can be observed that the introduction of a second ambulatory room reduces the physician workload. Process modeling and ABM proved to be suitable tools to simulate clinical processes and to provide insight on possible organizational changes.

An “in silico” Bench to Bedside Approach to Investigating Sepsis Biomarkers

Grace O'MAHONY^a, Christopher HAWTHORNE^a, Karl MCQUAID^a and Guillermo H. LOPEZ-CAMPOS^{a,1}

^a*Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, UK*

Abstract. Sepsis results in various patient complications and is due to a heightened inflammatory response against infection. This condition requires further exploration of biomarkers. We employed an “in silico” method comprised of text-mining and additionally clinical validation through the Medical Information Mart for Intensive Care. We highlight that Factor VIII shows potential as a pertinent septic shock biomarker..

Keywords. Biomarkers, Bioinformatics, Sepsis, Natural language processing

1. Introduction

Biomedical research is producing new data and knowledge at an unprecedented pace and is through an increasingly vast array of databases and data repositories containing a large variety of data contents and formats. This is leading to new avenues of research where it is possible to construct new experimental designs without needing to generate new data instead using the already existing published biomedical data.

Sepsis is a condition caused by an overwhelming widespread inflammatory response to infection resulting in massive deregulation of the immune response. Globally, sepsis occurs in approximately 10 per 1000 hospital patients, of which 30% of these patients develop multiple organ syndrome, 60-80% of progression to septic shock and mortality rates reaching 20% [1].

In this work we propose an “in silico” bench to bedside approach to analyse free-text data (also typically referred as “unstructured data”) extracted from publicly available resources which might facilitate the identification of sepsis biomarkers. The aims of this project are to identify molecular biomarkers using text mining approaches and then validating them in a clinical dataset combining different medical coding systems to gain deeper insights into this condition.

2. Methods

The initial stage of the project involved identifying relevant biomarkers for sepsis. For this purpose, we use an in-house developed methodology [2] that combines PubMed

¹ Corresponding Author,; E-mail: g.lopezcampos@qub.ac.uk.

queries and Pubtator annotations [3] using R. This approach enables us to retrieve chemical and other protein/gene biomarkers.

For clinical validation and analysis of the identified chemical biomarkers (encoded as MeSH or ChEBI terms) we used data from MIMIC-III, the 'Medical Information Mart for Intensive Care' [4], an openly available dataset comprising of de-identified health data collected from 61,532 intensive care unit admissions (53,432 adult patients stays and 8,100 neonatal), spanning from June 2001 – October 2012. Data collected from all aspects of ICU patient care includes patient details, vital signs, laboratory tests using LOINC coding and ICD-9 codes.

Relevant patients were selected using ICD-9 codes for sepsis, severe sepsis and septic shock and a set of non-septic controls involving different degree of inflammation from epilepsy (EPI) and ventilator associated pneumonia (VAP) diagnosis.

3. Results

5,566 chemicals, including many antibiotics and proteins, were retrieved from the initial analyses of the literature abstracts. Nine out of the top 20 occurring (as frequency in abstracts) potential sepsis biomarkers could be mapped to related LOINC codes. Those 9 codes were subsequently searched in MIMIC-III to check that they were present in the groups of patients of interest with sufficient sample sizes for statistical analysis. The LOINC code for Factor VIII fulfilled all the previous criteria and was chosen for analysis comparing sepsis samples and controls. We performed Mann-Whitney unpaired tests which yielded the following results "Sepsis vs EPI" $p=0.5714$; "Severe Sepsis vs EPI" $p=0.3928$; "Septic shock vs EPI" $p=0.04843$ and "Septic shock vs VAP" $p=0.04492$.

4. Conclusions

These results show that Factor VIII could be a potential element of interest to distinguish septic shock from controls and would be coherent with the development of coagulopathy in sepsis.

This still under development approach aims to integrate and automate an "in silico" bench-to-bedside platform for the analysis and eventually the validation of biomarkers in sepsis. This approach could be extended to other areas of interest in intensive care.

An Online Prevention Tool for Ophthalmological Disorders

Maria PATTE¹, Joseph LIASKOS, Parisis GALLOS and John MANTAS
Health Informatics Laboratory, School of Health Sciences, National and Kapodistrian University of Athens, Greece

Abstract. The information of the general population regarding the prevention of eye diseases is crucial. This work presents the design and development of an online prevention tool for the information and education of the general population about ophthalmological diseases. A literature review was conducted for the collection of all necessary and up-to-date information regarding the diseases selected. The phases of requirement analysis, design, development and evaluation were followed. The online tool developed, proved to accomplish the aims of usability and usefulness in the prevention of eye diseases and their complications.

Keywords. Ophthalmological Diseases, Prevention, Primary Healthcare

1. Introduction

The regular eye health monitoring plays a crucial role in the prevention and correct treatment of ophthalmological diseases [1]. Despite of the common belief that ophthalmological diseases are more frequent to elders, there are some diseases which appear to younger people and evolve over time [2]. Since an early diagnosis and treatment can prevent the loss of vision and other complications, it is necessary to educate the general population and raise its awareness of eye health [3,4]. The purpose of this work is to present the development of an online prevention tool which informs the general population about ophthalmological diseases.

2. Methods

The pilot online tool for the prevention of the ophthalmological diseases followed the phases of requirement analysis, design, development and evaluation. In the requirement analysis the functions of the tool were defined, and a literature review was conducted to collect all the necessary and up-to-date information regarding these diseases. 18 publications were used to structure the content of the tool. The criteria for the selection of the eye diseases were that they are very common and serious, they could lead to blindness if remained untreated, and their prevention is necessary and relatively easy. Based on the requirement analysis, an educational and instructional online tool was designed in order to serve the principles of usability, user-friendliness and usefulness. The language used had to be simple for the general population. A site map was structured,

¹Corresponding Author.; E-mail: mary_patte@hotmail.com.

and the most appropriate modules were chosen, according to the potential users' needs and the requested functions of the website. The Content Management System (CMS) technology was used in the development phase. Finally, an evaluation was conducted to assess the users' opinion regarding the usability and usefulness of the tool through semi-structured interviews. Three small focus groups were composed and the criteria of selecting the participants were their age, and their familiarity with technology or healthcare sector.

3. Results and Discussion

A pilot online prevention tool (for primary and blindness prevention) was developed in Greek language targeting the general population. The content includes informational and educational material concerning the anatomy of the eye, some of the most frequent eye diseases, specific eye exams, articles on various eye-related topics, as well as, advises and guidelines about eye diseases. Some examples of the eye diseases included are cataract, glaucoma, strabismus, age-related macular degeneration (AMD) and diabetic retinopathy. The users can perform a self-examination test for age-related macular degeneration. In addition, the user can request for more information or advice from experts through a form. A main menu in the site allows the navigation to all information and functions. The evaluation results concerning usability and usefulness were positive. All evaluators agreed that the website is easy to understand and navigate. They noted that the presentation of the information is simple, adequate, with no confusion, promoting education and prevention; they agreed that this tool promotes the awareness regarding the Ophthalmological Disorders. Healthcare professionals also mentioned that this tool can be useful for the clinical practice.

4. Conclusions

The described online tool targeting the general population contributes to the prevention of ophthalmological diseases in a simple and easy-to-use way. Compared to similar websites it includes related content. The inclusion of more ophthalmological diseases (e.g. refractive errors of the eye), audiovisual material, and "search" functionality for visiting ophthalmologists, are some of the limitations defined. Future work could include more content and interactivity with the user, as well as the usage of this tool on a larger scale.

Analysis of Professional Competencies for the Clinical Research Data Management Profession

Saly ABOUELENEIN^{a,1}, Tremaine WILLIAMS^a, Jaime BALDNER^a and
Meredith Nahm ZOZUS^{a, b}

^aUniversity of Arkansas for Medical Sciences, Little Rock Arkansas, USA

^bUniversity of Texas at Health, San Antonio Texas, USA

Abstract. Objective: This job analysis was conducted to compare, assess and refine the competencies of the clinical research data management profession.

Materials and Methods: Two questionnaires were administered in 2015 and 2018 to collect information from data managers on professional competencies, types of data managed, types of studies supported, and necessary foundational knowledge.

Results: In 2018 survey, 67 professional competencies were identified. Job tasks differed between early- to mid-career and mid- to late-career practitioners. A large variation in the types of studies conducted and variation in the data managed by the participants was observed.

Discussion: Clinical research data managers managed different types of data with variety of research settings, which indicated a need for training in methods and concepts that could be applied across therapeutic areas and types of data.

Conclusion: The competency survey reported here serves as the foundation for the upcoming revision of the Certified Clinical Data Manager (CCDMTM) exam.

Keywords. Professional competencies, clinical data management, SCDM

1. Introduction

The Society for Clinical Data Management (SCDM) is a non-profit organization for Clinical Data Management professionals. It published the first version of the Good Clinical Data Management Practices (GCDMP) in 2000 [1], and established the Certified Clinical Data Manager (CCDMTM) program in 2004. The job tasks of professional clinical data managers have periodically been surveyed to maintain the exam [2].

2. Methods

This survey was administered at the SCDM meeting, 23-26 September 2018, in Seattle WA. The tasks were obtained from previous surveys and job analysis work through the SCDM [2, 3].

¹ Corresponding Author.; E-mail: sabouelenein@uams.edu

3. Results

The response rate for our survey was 58.8%. The majority of the respondents 77.6% worked in private or publicly traded company. Respondents indicated a variety of organization types, the most frequently reported being pharmaceutical companies 38.7%. Eighty-two percent of the respondents indicated that they were practicing clinical data managers and 55% of the respondents indicated that they supervised clinical data managers. Respondents reported an average of 12.6 years working in clinical data management, and 16% of them reported being certified.

Most respondents (90.8%) managed data for randomized controlled trials (RCTs), but respondents also managed data for other types of studies. Respondents reported clinical data management tasks performed in their organization across the spectrum of design, programming, data processing, testing, project management, and training and review task domains. Future tasks they expected to perform included, risk-based monitoring, centralized monitoring, data visualization, maintaining awareness of new technology, new technology adoption, process improvement, metadata management, and data warehousing. At 77% and 74%, the respondents indicated data from personal wearable devices and data from home monitoring devices as types of data they expected to manage in the future.

4. Discussion

Our survey updated the previous professional job analysis and helps to monitor changes in work done by professional Clinical Research Data Managers. Changes between the 2015 and 2018 data confirmed a trend toward growth of the profession in terms to managing data for varied types of studies and data. This stands in contrast to the historical norms of data managers serving mainly one type of research and a limited variety of data. New tasks are consistent with application of basic informatics methods in clinical research contexts. This diversification calls for curricula and formal degree programs to educate Data Managers in general principles and methods that can be applied to new research settings, studies across the continuum of clinical research and varied types and sources of data.

5. Conclusion

The results of this study serve as the foundation for the Certified Clinical Data ManagerTM exam and inform the scope of the practice standards for the profession, the GCDMP.

Application of IBM Watson to Support Literature Reviews: A Preliminary Experience in Restorative Dentistry

Giacomo DERCHI^a, Marco VISENTIN^b, Vincenzo MARCHIO^a, Lisa LARDANI^a, Antonio BARONE^a, Marco PRENASSI^b, and Sara MARCEGLIA^{b,1}

^aUniversità degli Studi di Pisa, Pisa Italy

^bUniversità degli Studi di Trieste, Trieste, Italy

Abstract. Literature reviews are crucial in the choice of the best personalized material type and restauration type in restorative dentistry. We developed an IBM-Watson based system to support literature search for restorative dentistry, and compared its results to a literature search performed by a trained professional. We found that our system could assist the researcher in performing a literature review, but the grounding semantic model needs to be refined in order to provide more extensive results.

Keywords. Literature review, restorative dentistry, cognitive computing.

1. Introduction

Technology for restorative dentistry is becoming more and more advanced, and new techniques and materials have been introduced to obtain minimally invasive treatments and better outcomes[1]. When choosing the best solution for patients, clinicians should rely on the available growing evidence. In this scenario, a system supporting the process of literature review[2] will optimize the choice of materials for restorations, and, in turn, the patient's quality of life. To this end, we tested the ability of IBM Watson cognitive computing services to provide the ground engine for a system supporting dental inlays literature search process.

2. Methods

PubMed API were used to run the literature search. A concept model was developed and trained in IBM Watson Knowledge Studio using 42 annotated documents (review papers on dental inlays). The service uses proprietary natural language processing methodologies. The precision of the system (percentage of true positives on the overall positives recognized by the model) and the recall (percentage of true positives on the overall true from the ground truth) were used as performance measures of the model. The model was then implemented in IBM Watson Discovery in order to process PubMed abstracts and to retrieve the concepts, relationships, and specifications according to the semantic model. A user interface developed using Node-Red[3] allows the clinician to visualize the sentences (and abstracts) more relevant to the research question related to the restauration type, the material type, and the characteristics. The

¹ Corresponding Author,; E-mail: smarceglia@units.it.

system was validated comparing the literature review automatically performed with the literature review performed by a trained clinician, in terms of number and relevance of papers retrieved.

3. Results

The semantic model included 15 main entities (among them, “restauration type”, “material type”, “character”, “comparator”, “value”) and 13 main relationships and achieved an overall precision of 93% and an overall recall of 80%. In Watson Discovery, a total of 165 documents (abstracts) were processed using the general PubMed query. The system was tested with the aim to identify the papers relevant to establish the longevity comparison between composite inlays and ceramic inlays. The first man-made search yielded a total of 24 unique papers, 8 of which were included. The first search made by IBM Watson yielded a total of 18 unique papers, 9 of which were included. The two searches obtained completely different results, with only 3 papers found by both the human researcher and IBM Watson, but all of them potentially fit to be included in a literature review.

4. Conclusions

These preliminary results show that IBM Watson could be used to assist the researcher in performing a literature review, but the model on which Watson is trained needs to be refined in order to provide more extensive results. These findings will help to further refine IBM Watson's abilities and getting closer to obtaining a Cognitive Computing Platform able to answer clinical questions made by Dental professionals

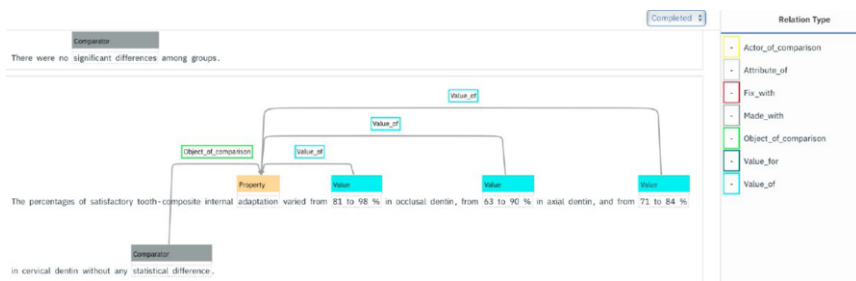

Figure 1. Text annotation in Watson Knowledge Studio with the defined semantic model.

The Impact of Information Quality on Retracted Bioinformatics Literature

Austin SPRINGER^a, Donna CHACHERE^a, Awaad ALSARKHI^a, and Meredith ZOZUS^a

^aUniversity of Arkansas at Little Rock

Abstract. One of the biggest challenges facing biomedical research today is the lack of reproducibility in findings. In response, a growing body of literature has emerged to address this. However, much of this focuses on bias and methods, while little addresses the issue of information quality. The purpose of this poster is to determine the role of information quality for retracted bioinformatics literature.

1. Introduction

Irreproducibility continues to be one of the more emerging issues in recent biomedical research. Much has been written about its negative impact on the progression of biomedical science and ultimately patients [1], with guidelines proposed [2,3]. Few of these, however, address the impact of low information quality (IQ). In this poster, the IQ issues found in retractions are discussed, and corresponding patterns analyzed.

2. Method

The Retraction Watch database [4] was filtered by: Retraction or other Notices From Date value 1/1/2018, To value 12/31/2018, and Reason(s) for Retraction value “Concerns/Issues About Data” which resulted in 124 retractions with fields such as Subject, Journal, Publisher, Original Paper Date, Retraction date, and Country. Of these, 119 were classified for associated IQ dimension by 2 independent coders. After obtaining the Scimago Journal Rank of each record, statistical analysis was then done.

3. Results

54% of retractions were due to the Believability dimension of IQ. China was the most prevalent country being involved in 32% of all records, followed by India 24%, and the U.S. 19%. SJR score comparisons indicate records involving the top 2 IQ reasons (Believability & Wrong data used) are associated with higher-ranking journals ($p = 0.05$), as well as significant differences between regions ($p = 0.02$). Articles published in the U.S. & Canada through publishers other than Elsevier, PLoS & Springer were 3.3 times less likely to be associated with Believability than all other articles ($p = 0.05$). Survival analysis indicates studies having Biochemistry as a subject have a half-life of 33.8 months and remain in publication longer than those with other subjects.

Figure 1. the association of higher journal scores with the top 2 IQ issues.

Table 1. Articles least associated with Believability

	Believability	All other issues
U.S. & Canada articles not published by Elsevier, PLoS & Springer	4	10
All other countries & publishers	60	45

Figure 2. survival analysis showing how those with Biochemistry subject remain in publication longer.

4. Discussion & Conclusion

Our aim was to investigate what role IQ plays for retracted bioinformatics studies. While Believability is the most prevalent, others are associated with countries, subjects, and longevity in months published. Future work could involve expanding to a wider date range, as our study design was limited to calendar year 2018.

Association of C>U RNA Editing with Human Disease Variants

Sapan MANDLOI^{a1}, Zackary FALLS^a, Rong DENG^b, Ram SAMUDRALA^a, Peter L. ELKIN^{ac}

^a Department of Biomedical Informatics, University at Buffalo, Buffalo, NY, USA

^b Jacobs School Of Medicine And Biomedical Sciences, Buffalo, NY, USA

^c Department of Veterans Affairs, VA Western New York Healthcare System, Buffalo, NY, USA

Abstract. RNA-editing is an important post-transcriptional RNA sequence modification performed by two catalytic enzymes, "ADAR"(A>I) and "APOBEC"(C>U). Although APOBEC-mediated C>U editing has been associated with a number of human cancers, the extent of C>U editing in human disease remains unclear. Here, we performed an association study and found that at least 1293 human disease variants occur at sites predicted by sequence motif analysis (RNASee protocol) to undergo APOBEC3A/G C>U editing. These variants were associated with a wide array of human disease conditions ranging from cancer, metabolic disorders, retinopathies, cardiomyopathies, neurodegenerative disorders and immunodeficiencies. These results indicate that APOBEC mediated C>U RNA editing may have widespread and previously unreported contributions to human disease conditions..

Keywords: RNA-editing, Protein diversity, Cytidine deaminase

1. Introduction

RNA-editing is an important post-transcriptional RNA sequence modification performed by two catalytic enzymes, "ADAR"(A>I) and "APOBEC"(C>U)¹. An emerging body of research has implicated APOBECs playing important roles in human disease processes such as cancer^{2,3}, Alzheimer disease and primary pulmonary hypertension⁴. Although A>I RNA editing has been widely studied, the extent of C>U editing in human disease processes is still largely unclear, and no comprehensive database yet exists for C>U editing events. Using the features of the experimentally verified RNA editing sites, we have developed a program to predict editing sites and compared with existing gene-disease-variant information to further assess the extent to which C>U editing may contribute to human disease.

2. Methods

2.1 Predicting C>U RNA editing sites and data collection

The RNASee platform (<http://128.205.176.246/masee/>) identifies tetra-loop sequences by scanning the mRNA sequence (12789 CDS fasta sequence collected using UniProt REST services) with a four nucleotide loop (0-3) sliding window in order to identify target sequences containing a CC at the 2-3 positions. The secondary structure of the sequence containing putative C>U editing site for APOBEC3A and 3G is then predicted using ViennaRNA (<https://www.tbi.univie.ac.at/RNA/>) and the resulting energy is used to support the structural stability. We compared the RNAsee list to the humsavar human variant list from UniProtKB/Swiss-Prot. We found 30705 (39%),

¹ Corresponding author; Email: sapanman@buffalo.edu

40035 (51%), 8081 (10%) total variants are classified as human disease variants, non-disease associated variants (polymorphism), and indeterminate variants respectively. We identified 1278 functional sites from UniProt-SwissProt database (from 206/734 genes/proteins), consisting of 9% active sites, 19% binding sites, 54% glycosylation sites and 18% metal-ion binding sites.

3. Results

3.1 Predicted RNA editing sites are associated with known human disease protein variants and pathway analysis

RNAseq generated a list of TOP25 ranked probable C>U RNA edit sites, associated with 78852 human variants and 12789 genes. A comparison of C>U RNA editing sites with known human-variants found 1293 out of 30705 (4%) variants and 734 genes were associated with known human disease processes, 1828 out of 40035 (5%) variants were associated with polymorphisms and 191 out of 8081 (2%) variants were unclassified. The top 5 most frequently diseases and genes associated with C>U variants are listed in Table 1. Pathway analysis showed enrichment of angiogenic, hematologic and hypoxia-induced processes, consistent with recent in-vitro studies⁵. In addition, we identified functional sites of metabolically essential proteins, including FGFR1, GALNS, G6PC and FTO, suggesting these editing events may have direct impact on protein function.

Table 1: Top 5 associated diseases and genes

Genes(# associated diseases)	Disease (# associated genes)
TP53 (6)	Pheochromocytoma (9)
VHL (6)	Dejerine-Sottas syndrome (6)
CDKN2A (5)	Diabetes mellitus, permanent neonatal (6)
G6PC (5)	Li-Fraumeni syndrome (6)
FGFR1 (5)	Sporadic cancers (6)

Figure 1: List of pathways

4. Conclusions

In this study, we were able to predict a large number of previously unidentified APOBEC mediated C>U editing sites across the human transcriptome and associate them with a wide array of human disease conditions. Our results suggest that APOBEC-mediated C>U editing may play a key role in hypoxia-induced remodeling during oncogenesis. In future research will apply our analysis to the transcriptomes/proteomes of specific disease conditions in order to further clarify the functional and predictive role of APOBEC mediated C>U RNA editing in human disease.

Keywords. Glioblastoma, Neural Networks, Expert Systems

1. Introduction

Glioblastoma multiforme (GBM), the most common type of malignant brain cancer in adults, has a poor prognosis with a median survival of around 15 months despite aggressive treatment.[1] GBMs are very heterogeneous tumors that differ in morphological and genetic aspects. Due to the genetic diversity, subtypes are described in the literature, that differ in their prognosis (a classical, mesenchymal, proneural, and occasionally neural subtypes).[2] Modern machine-based methods have a large potential for the automated analysis of medical images and are successfully used in neuropathology. [3] This study investigates if a neural network can automatically measure the heterogeneity of GBMs and can support prognosis estimates in a clinical setting.

2. Method

57 tissue samples of glioblastoma (Isocitrate dehydrogenase (IDH)-wild-type) have been fixed in 10% formalin and embedded in paraffin. 2 µm thick slices were stained with hematoxylin and eosin. 35 samples from brains from autopsies without pathological abnormalities have been prepared as a reference.

Slides were scanned using an Aperio AT2 scanner. Next, tumor tissue was digitally labeled and separated from the surrounding brain tissue. The first step will be to train a neural network for the delamination of GBM tissue from healthy tissue. As a next step, an additional neuronal network will be trained to identify the degree of

¹ Corresponding Author, Michael Oertl, E-mail: michael.oertl@hs-neu-ulm.de

morphological heterogeneity of glioblastoma. This data will be backed up by immunohistochemistry and presented as a color-coded image. A Convolutional Neural Network (CNN) will be developed and trained because it has already been used successfully on classification tasks for image analysis.[4]

3. Results

92 images have been investigated, which have an average size of 6 GB and overall 552 GB of data that needed to be processed. Input for the neuronal network is always a small area of the regarded image. The network shall classify this area. After every step, the area is shifted by a stride. The shifting enables us to keep the network smaller as we train on smaller data samples, and with this technique, we generate a vast amount of training data. For example, if we have an image with 70.000x40.000 pixels and the area we want to classify has the size of 200x200 pixels, and we shift the area by 100 pixels in each step, we have generated 278.901 training samples from one image. The output is a probability distribution over the possible classes. Firstly, these classes are GBM and non-GBM, and in the second step, the classes will be over the heterogeneity of the tumor.

4. Discussion

The authors suppose that a higher heterogeneity in the tumor tissue is related to worse survival chances of the individual. The application of neuronal networks for the neuropathology is still at its beginning. Nonetheless, automatic measures of the histological tumor heterogeneity could lead to more precise predictions and therefore, also to individual risk-adapted therapies over the long term.

5. Conclusion

We presented a new method for GBM detection and classification. This method enables a faster and automated tumor detection, as well as classification on the tumor to enhance individual prognoses.

Abstract. Analyses of nerve histology are core assays in basic and applied research and even in clinical setting. Detailed report on nerve morphology may unbiasedly indicate the current state of a peripheral nerve. Manual method requires trained technician and is a time-consuming procedure. Available plugins to well known image processors are limited in use and data outcomes. Thus, the aim of the study was to create a tool for fast and repeatable analysis of a nerve section image. As a results we get very high precision of analysis in shorter time.

Keywords. Axon evaluation, Neural network

1. Introduction

Preclinical research of neuroregeneration requires assessment of nerve fibers histology. The most reliable results contain histomorphometry parameters of axons and myelin sheaths. Manual methods are prone to human error and are time consuming. Computer-based techniques may improve the above and deliver the accuracy comparable with a experienced researcher. The study aimed to prepare a neural-network MATLAB script, with a novel approach to contrast-based method used for whole nerve section analysis.

2. Materials and methods

Semithin sections of a rat sciatic nerve stained with toluidine blue were a input data. They were scanned at 40x magnifications. Firstly, the analysis includes grey-scale conversion and contrast improving modifications e.g. CLAHE. Unlike other described methods, which analyze objects after binarization, we worked with the grey-scale image. Objects found with regionprops function were then filtered. Our protocol offers manual verification and removal of false-positive objects. We also applied Neural Net Pattern

¹ Corresponding Author E-mail: wikt.paskal@gmail.com

Recognition from Matlab for filtering results. Then, a rectangle enclosing each border of an object was defined. From the center to the edge of the acquired area line segment was lead and histogram on this length was set. The border of each axon was determined in the point of highest contrast between neighbour pixels. The borders of myelin sheaths were defined likewise. This operation was repeated 360 times, around the analyzed nerve cell (radial histogram scanning and thresholding). The method resembles manual analysis since local contrast is used to mark the axon.

Finally, the main morphometric parameters may be determined (radius, G ration, thickness, area etc.). Results were compared with manual measurements of 28 random nerve images, estimated by 3 researchers in ImageJ. Comparison to manual data was shown as ratios: script: manual.

3. Results

After optimization of brightness and contrast parameters, axon area overlay at level 1,001 and 1,009 of the myelin sheaths was achieved. Paired T-test showed no significant differences between these two methods (p -value = 0,321). Use of Neural Net enables to reach 93,6% of accuracy of axons recognition vs 3 researchers. A run time of the script is about 12 times shorter than the manual method.

4. Discussion

Other similar methods consist of binarization, which doesn't allow to define borders of the nerves precisely. The script presented shows a new approach to this case. It is based on reconstructing the way of evaluation done by the scientist. The presented script shows a new approach to this case. Our idea is based on reconstructing the way of evaluation done by the scientist. Owing to this innovative idea, the higher level of accuracy of computerized evaluation is possible. The most depending factor is optimising the differentiation between correctly and incorrectly marked borders. Further researches focus on increasing the efficiency of this protocol. In conclusion, the presented script performs an accurate analysis of nerve sections on a grey-scaled image. It overcomes bias of a binarization. The method decreases time of analysis and remains repeatable.

Automatic Detection of Vital Signs in Clinical Notes of the Outpatient Settings

Martín DIAZ MAFFINI^{1a} and Fernanda AGUIRRE OJEA^a and Matías MANZOTTI^a

^a*Health Informatics Office, Hospital Alemán, Argentina*

Abstract. The determination of vital signs is a fundamental aspect of patient care. Electronic health records have a structured format for their registration. It is known that the frequency with which this data is recollected is not representative of reality. To complement the missing data we have created a tool that extract the information regarding blood pressure, heart rate, respiratory rate, height, weight and pain level recorded in free text in the clinical notes of outpatients.

Keywords. Natural Language Processing, Vital Signs, Electronic Health Records

1. Introduction

The determination of vital signs is a fundamental part of patient care in order to control, maintain or modify the therapeutic measures carried out. Most electronic health records have a structured format for the registration of this information, however, the frequency with which this data is recorded is not representative of reality [1]. Electronic health records capture data in two ways: in a structured format and in free text format. For the use of clinical data for secondary purposes the data must be structured. However, the exclusive approach of structured data for the entry of clinical data can result in the loss of significant information that is usually entered in free text format. [2,3] To complement the data of vital signs missing from the clinical notes we have created a tool that extracts this information regarding blood pressure, heart rate, respiratory rate, body temperature, height, weight and pain level recorded in free text of the clinical notes of outpatients.

2. Methods

The system extracts mentioned vital signs from the text of the clinical notes. These texts typically include ad hoc abbreviations, common words and spelling errors. In order to create the extraction system, a set of clinical notes was manually annotated by experts and analyzed to infer patterns. Such patterns were coded as regular expressions, each with a degree of specificity. The system attempts to detect vital signs by first applying more specific rules and then testing more generic rules along with additional validity checks to exclude false positives. The application of more sophisticated machine learning techniques was evaluated but rejected due to the requirement of both high precision and false positive detection in this specific problem. The results of these patterns and rules

¹ Correspondent author: martindiaz@hospitalaleman.com

in the clinical notes were evaluated by experts, who tried to find opposite examples and then refine them in an iterative way to increase accuracy and recall. The system was implemented within the UIMA (Unstructured Information Management Architecture)[4]. The analysis of each clinical note is comprised by several phases: first a phase where grammatical sentences are divided, followed by a tokenization phase which aims to detect running words and, finally, a vital signs detection phase. The detectors of each vital sign are implemented as independent components that the tool calls during the start of the process, so the tool is scalable and should be able to access new future components when available.

3. Results

For the phase of manual registration of vital signs in the clinical records, 3960 representative clinical notes of the different specialties that record information in search of the vital signs were evaluated. We identified in the free text: 2 records of pain level (PL), 101 heart rate (HR), 22 respiratory rate (RR), 35 body weight (BW), 225 blood pressure (BP), 7 of height (HT) and 53 of body temperature (BT).

Different configurations of the extraction tool were tested until obtaining a specificity and sensitivity of 100% against the training set.

The tool was implemented in such a way that it would be executed after 5 seconds of inactivity of the medical user in the outpatient electronic health record. The registration rate of structured vital signs data was measured one year prior to implementation and measured again after implementing the tool. The results were as follows: HR 448 occurrences, RR 122, BW 6935, BP 4156, HT 2610, BT 82, PL 15 and HR 4444, RR 1084, BW 8289, BP 9820, HT 3786, BT 1472, PL 1230 respectively. Increases were registered in the PL record 82 times more, BT 18 times more, HR 10 times more, RR 9 times more, BP 2.5 times more, HT 1.5 times more and BW 1.2 times more.

4. Conclusions

Vital signs registration in clinical notes is presented in patterns which can be determined and, therefore, rules can be developed to achieve their extraction by using tools that help achieve greater completeness of the records. The use of these tools increases the structured registration of these data, enabling their subsequent secondary use in clinical decision making.

Best Practices for Designing Discrete Choice Experiments and the Use for Older Adults with Cognitive Impairment

Thomas ENGELSMA^{a, b, 1}, Monique W. M. JASPERS^{a, b}, Anne M. TURNER^{c, d}

^a Center for Human Factors Engineering of Health Information Technology,
^b Department of Medical Informatics, University of Amsterdam, Amsterdam, The Netherlands;

^c Department of Health Services, School of Public Health, University of Washington, Seattle, WA; ^d Department of Biomedical Informatics and Medical Education, School of Medicine, University of Washington, Seattle, WA.

Abstract. *Objective:* the aim of this scoping review is to 1) identify guidelines, frameworks, issues, and recommendations regarding the development of a discrete choice experiment (DCE), 2) look at potential design considerations regarding the development of a DCE for older adults with dementia, and 3) summarize knowledge about the current inclusion of and experiences with older adults with cognitive impairment in DCE studies. *Methods:* Two literature searches divided into two topics were performed in PubMed, CINAHL, and PsycINFO. *Results:* Topic 1 found 19 articles regarding frameworks, guidelines and design considerations for DCEs in healthcare. Topic 2 found eight articles regarding the effect of cognitive impairment on DCE results and/or discussing the inclusion of cognitive impaired older adults in these DCE studies. *Conclusion:* There is minimal literature available regarding the effect of cognitive impairment on DCE results. In future studies we will explore if DCEs can be used to involve older adults with dementia in decisions regarding transitions in care.

Keywords. Discrete choice experiment, design, older adults, cognitive impairment

1. Introduction

There are a growing number of older adults worldwide. Older adults are at increased risk of developing cognitive problems and dementia. Management of dementia often requires making a variety of important care-related decisions. These decisions often occur without the input of the older adult suffering from dementia or another severe illness [1]. It has been shown that including older adults with dementia in decision-making can lead to an improved well-being and reduce dementia-related symptoms [2]. This literature review was conducted as preliminary work to inform the development of a DCE-based tool for older adults with dementia to support their participation in the decision-making process.

¹ Corresponding Author email: t.engelsma@amsterdamumc.nl

2. Methods

We conducted two literature searches regarding DCEs. The first topic (Topic 1) focused on lessons learned from applications of DCEs in healthcare. The second topic (Topic 2) focused on DCE studies including older adults with cognitive impairments. PubMed, CINAHL, and PsycINFO were searched for both topics. Studies had to be published within 2009-2019 and written in English. For inclusion in Topic 1 articles had to discuss the design process of a healthcare-related DCE. For Topic 2, articles were included that 1) describe DCE studies targeting older adults (65 and over) and 2) discussed the effect of cognitive impairment on DCE results and/or mentioned cognitive impairment in their inclusion process.

3. Results

A variety of frameworks, guidelines, and design considerations were identified in Topic 1 that might be useful when developing DCEs for older adults with dementia, such as using visuals. Minor literature regarding the effect of cognitive impairment on the results of a DCE was found in Topic 2. The few studies involving the use of DCE in older adults with cognitive impairment, suggest that older adults with mild cognitive impairment are equally capable of giving meaningful responses compared to those who are cognitively intact. However, these studies had a small sample size. A small number of studies discussed how they went about including older adults with cognitive impairment in their DCE. Most of these studies involved individuals with only mild cognitive impairment based on a cognitive assessment, or based inclusion on the opinion of professionals or ability to provide informed consent.

4. Discussion and Conclusion

This scoping review summarized insights on DCEs in healthcare with the aim of informing the design of a DCE for older adults with dementia. We found that in healthcare related context a minority of researchers included older adults with cognitive impairments in their DCE. Older adults with more severe levels of cognitive impairment are either completely excluded from participation in DCEs, or proxies (usually caregivers) participate in the DCE. However, studies suggest that caregivers' preferences regarding healthcare often differ from the recipient's preferences [3]. Therefore, DCE data may not be reliable when using proxies. In future studies we will explore if DCEs can be used to involve older adults with dementia in decisions regarding transitions in care. The final aim is to develop a DCE- based digital decision-making tool for older adults with dementia and their caregivers.

Biostatistics Disruptive Acculturation Through Serious Gaming: A New Hope

Pierre GILLOIS ^{a,1}, Lionel DI MARCO ^a, Josep M. NICOLÀS ^b,

Alexandre MOREAU-GAUDRY ^a, Anne EGO ^a, Sandra DAVID-TCHOUDA ^a,

Donald K MARTIN ^c, Jean-Luc BOSSON ^a

a CNRS / TIMC-IMAG Lab., UMR 5525 (Themas), Grenoble-Alpes University, France

b IDIBAPS, University of Barcelona, Barcelona, Spain

c CNRS / TIMC-IMAG Lab., UMR 5525 (SyNaBi), Grenoble-Alpes University, France

Abstract. Biostatistics is one of the transversal subjects that all future doctors must acquire and master. Nonetheless, it is a subject that has the reputation of being difficult, which has not been able to be corrected even with the application of new pedagogical methods such as blended learning. We address this problem with our acculturative and disruptive approach in the form of a serious game scenario in clinical research that integrates biostatistics with our R4Web adapted tools. Our approach was launched in 2008 for the second year of medical school. Here we describe this LOE scenario for serious game including the biostatistics disruptive acculturation task and present its new international version.

Keywords. “Schools, Medical”, Bio-statistics, Serious games, “Education, Public Health Professional”, “Games, Experimental”, “Data Interpretation, Statistical”

1. Introduction: Learning context

Some subjects are part of these transversal competencies that all modern health professionals must master. Biostatistics is one of those competencies, that provides the necessary foundation for understanding and analysis in all health fields whether through the critical appraisal of articles (CAA). Major efforts have been made to integrate this transversal subject into the initial medical training in the form of a revised pedagogy using e-learning, blended learning, etc. [1,2].

Thus, it behoves health educationalists to develop pedagogical strategies that overcome the barrier of disinterest and misunderstanding on the part of students, who often consider it too mathematical, useless for health and medical practice and do not realize its underlying and real importance for their professional lives. To overcome this challenge, in 2008 a serious game simulating a clinical research process has been developed in Grenoble. The serious game scenario is called “LOE” (Laboratorium Of Epidemiology) is hosted on the multilingual health Grenoble Serious Games platform: Professional Health Fantasy (<https://prohf.org>).

¹ Corresponding Author,: pierre.gillois@univ-grenoble-alpes.fr.

2. Materials: Serious game scenario description

Provided by the platform, interaction activities of the scenario are integrated in the form of online forms, emails, integrated pseudo websites such as the Medical Information Department for the data request, or the International Conference for the final step. Collaborative activities for students, groups or tutors are also supported by the platform. This platform therefore centralizes all the information and the digital tools required to simulate clinical research in all these dimensions.

This LOE serious game scenario immerses students in a public health physicians' situation, since it involves investigating the incidence of a disease: venous thromboembolic disease (VTE) and that includes all the steps required to undertake a real clinical research program. The main objectives for students of this situation are to (i) design the protocol and implement an epidemiologic study, (ii) prepare and submit a scientific paper including the biostatistical analysis task (with the adapted R4Web tool: <https://r4web.univ-grenoble-alpes.fr>), to describe the protocol and epidemiological study, for presentation at a simulated conference; (iii) finally propose a decision-making tool to optimize the VTE diagnostic process.

3. Practice Analysis: User experience

By discovering the game, the learner will wander through the various virtual tours of the group's hospitals to discover the units, services, resources and tools at his disposal for the mission. The IT environment is designed to stage different interactions with scenario characters in the game, such as patients in the hospital, PPC experts, members of the conference scientific committee, etc. This in order to help students to take on different challenges and acquire skills related to the scenario, by engaging into the game. Over time of the game, the students are judged on the quality of their production: protocol, article and keynote. The role of the teachers as tutors is to only guide the learners during the classroom sessions. The success of this serious game depends on the need for involvement and commitment of both learners and tutors. The challenge is that learners and tutors must leave their comfort zone and must go beyond with their computer.

Finally, informal feedback from our clinical colleagues is that the tools that utilise real research projects provide immediate and positive implications for the young doctors in-training. All the feedback reinforces the benefits of this new approach, so that biostatistics is no longer an unavoidable cliff but just a fun step as part of an overall clinical health research process. This active approach to problem-based learning is necessarily more "disruptive" for students and a challenge for tutors.

Challenges of In-House Development and Implementation of a CPOE for Oncology

S. de MATOS LIMA^a, C L GIMENEZ^a, D. LUNA^a

^a *Department of Health Informatics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Abstract. Hospital Italiano de Buenos Aires (HIBA) is an academic tertiary care hospital highly specialized that has started the process of informatization of chemotherapy protocols. The objective is to describe the development of a computerized physician order entry (CPOE) oriented to the oncology adult patient and the members of the healthcare team that works with him (physicians, pharmacists, nurses and administrative staff) to improve the process and prevent errors at a critical point in the patient's health care: during prescription, preparation and / or administration. The development of this system consisted of several stages: inquiries about the usual work and perception of needs of the potential users; user-centered design; interoperability with the electronic health record (EHR) and development of a final prototype

Keywords. CPOE, oncology, chemotherapy

1. Introduction

The oncological patient represents a healthcare challenge [1] Patient safety is of vital importance and this is where information systems can reduce the rate of errors and adverse events. [2] The prescription cycle in oncology turns out to be complex due to the coexistence of multiple structured schemes and the high toxicity of drugs.[3] The benefits of implementing a CPOE for indication of medications have been described, from the reduction of errors to integration of clinical decision support systems. [4] and some have shown their long-term benefit [3, 4] One of the challenges in oncology is to prevent errors that may occur during the different phases of the prescription cycle[5] Some appears to be associated with more significant adverse outcomes, with approximately one third of all errors identified as serious or life-threatening [5]. Methods A descriptive observational study was carried. The study is a mixed design, with a qualitative and quantitative approach.

2. Results

In October 2012 we started to develop and implement a CPOE integrated into the hospital's EHR, planning to incorporate pediatric patients at a later stage [7] For the start a surveyed and meetings were held between the project team. In a first stage in the standardization of order sets we start working in spreadsheet format for a year. The team was made up of one health informatics specialist, one process analyst and two developers. Six people participated in the preparation committee of order sets: one clinical oncologist, one hematologist, one gynecologist, head of oncology pharmacy, and oncology nursing supervisors. This phase lasted 7 months. By July 2013, the 50 most used protocols in the institution were completed, agreed between the prescribing services, oncology pharmacy

and nursing. In October 2013 there were 100 standardized protocols. The second stage began with the development of the RCM to structure the order sets, add agendas in the ADT for the sectors that treat cancer patients, connect the prescription module with the pharmacy administration system (PAS), incorporate the preparation processes of the oncology pharmacy into the PAS, and modify the EHR to allow the prescription of oncological protocols. Finally, the design was completed and it was implemented in November 2014.

3. Discussion

Protocols were added up until reaching almost all of those available for adults. The implementation was followed by a process of continuous improvements and system adjustments that allowed a superior user experience and avoid frequent errors that were detected. As a strength, the in-house development that allowed the system to adapt to the previous workflow and fully interoperate with the HER.

4. Conclusions

We have described the process of implementing a CPOE of chemotherapy in a high complexity hospital with its own development team and how it was arrived from a paper model to another that interoperates with 4 simultaneous systems in a complex circuit in which physicians, pharmacists, nurses and administrators interact in different stages, which are often critical for the patient.

Classification of Biceps Brachii Muscle Fatigue Condition Using Phase Space Network Features

Navaneethakrishna MAKARAM^{a1} and Ramakrishnan SWAMINATHAN^a

^a*Non-Invasive Imaging and Diagnostics laboratory, Department of Applied Mechanics
Indian Institute of Technology Madras, Chennai, India - 600036*

Abstract. In this, study, an attempt is made to differentiate muscle nonfatigue and fatigue condition using signal complexity metrics derived from phase space network features. A total of 55 healthy adult volunteers performed dynamic contraction of the biceps brachii muscle. The first and last curl are segmented and are considered as nonfatigue and fatigue condition respectively. A weighted phase space network is constructed and reduced to a binary network based on various radii. The mean and median degree centrality features are extracted from these networks and are used for classification. The results of the classification indicate that these features are capable of differentiating nonfatigue and fatigue condition with 91% accuracy. This method of analysis can be extended to applications such as diagnosis of neuromuscular disorder where fatigue is a symptom.

Keywords. Muscle fatigue, Phase space networks, Multilayer perceptron

1. Introduction

Neuromuscular fatigue can be defined as a task-induced reduction of the force-generating capacity of a muscle. Surface Electromyography (sEMG) signal reflects the occurrence and progression of muscle fatigue. Conventional signal processing techniques fail to quantify muscle fatigue. In this study, nonlinear features are extracted using phase space networks to explore the dynamics of the complex biological system.

2. Methods

The study involves subjects performing biceps curl exercise with a six kilogram force dumbbell until fatigue. During this period sEMG signals are recorded from the biceps brachii muscle in accordance with the SENIAM standards. A data acquisition rate of 10ksp/s and a gain of 1000 is used. These signals are preprocess with a 10-400 Hz band pass and a 50 Hz notch filter. The first and last curl are extracted based on the methodology mentioned in [1]. The phase space is constructed based on Takens embedding procedure with a dimension of 3 using false 1 neighborhood procedure.

¹ corresponding author: email kmakaram@yahoo.com

The weighted phase space network is constructed based on the following criterion [2].

$$W_{ij} = |X_i - X_j| \tag{1}$$

Where, W_{ij} is the adjacency matrix, and, X_i and X_j correspond to the instance in the phase space and represent a node. The binary network is constructed by using the following condition:

$$W_{ij} \leq r \tag{2}$$

Here, the threshold value r ranges from 0.05 to 0.5 in steps of 0.05 times the standard deviation of the signal. This binary network degree distribution is computed. The mean and median degree centrality measures are extracted. The classification is performed using a multilayer perceptron (MLP) algorithm and a 10 fold cross validation scheme.

3. Results and Discussion

Figure 1. Representative adjacency matrix obtained with an r value of 0.25SD (a) nonfatigue and (b) fatigue

In figure 1, the adjacency matrix obtained from a subject in nonfatigue and fatigue condition is shown. It is seen that the fatigue condition has a greater number of connections. The centrality features indicate the presence of a greater number of recurrent (similar) patterns in fatigue. The classification performance of the extracted features are shown in table 1. It is seen that mean degree centrality and median degree centrality separately perform well with an average accuracy greater than 85%. When both these features are used in conjunction an accuracy of 91% is obtained. It is to be noted that Median centrality feature alone gives similar performance where in a single subject is misclassified in this case leading to the disparity in the performance.

Table 1 Classification performance of MLP for various features

Features		Sensitivity	Specificity
Mean Centrality	85.7	85.7	85.7
Median Centrality	89.3	87.9	90.7
Both	91.0	89.7	92.6

Classification of First-Episode Schizophrenia Using Wavelet Imaging Features

Kateřina MARŠÁLOVÁ^{a,b}, Daniel SCHWARZ^{a,b} and Ivo PROVAZNÍK^c

^a Masaryk University, Faculty of Medicine, Kamenice 5, 62500 Brno, Czech Republic

^b Institute of Biostatistics and Analyses, Ltd., Czech Republic

^c Brno University of Technology, Technická 3058/10, 61600 Brno, Czech Republic

Abstract. This work explores the design and implementation of an algorithm for the classification of magnetic resonance imaging data for computer-aided diagnosis of schizophrenia. Features for classification were first extracted using two morphometric methods: voxel-based morphometry (VBM) and deformation-based morphometry (DBM). These features were then transformed into a wavelet domain using the discrete wavelet transform with various numbers of decomposition levels. The number of features was then reduced by thresholding and subsequent selection by: Fisher's Discrimination Ratio (FDR), Bhattacharyya Distance, and Variances (Var.). A Support Vector Machine with a linear kernel was used for classification. The evaluation strategy was based on leave-one-out cross-validation.

Keywords. Machine learning, neuroimaging, schizophrenia, support vector machines

1. Introduction and methods

Machine learning offers promising methods for computer-aided diagnosis of neuropsychiatric disorders. The use of these computing methods is highly desirable, as they have the potential to create an objective process of early diagnosis and prognosis. This research explores the design of the classification algorithm and the application of wavelet transformation to image data. Our proposed algorithm follows the ideas in [1]. Compared to the original algorithm, the main advantage of our version lies in the ability to carry out more experiments with different decomposition levels by wavelet transform.

The algorithm consists of five main steps: (i) Two types of preprocessing were used to extract features: VBM (gray matter densities) and DBM (local volume changes), (ii) images were decomposed by wavelet transformation into another domain. It was necessary to specify two parameters: decomposition levels and mother wavelet (sym5) [2], [3], (iii) the number of features was reduced by the experimentally determined thresholding of absolute values smaller than 0.05, (iv) the number of features was reduced by selection. Three different metrics were used for this: FDR, Bhattacharyya distance, and Var., (v) the classification into two groups (FES/NC) was carried out. The algorithm was tested on a dataset provided by The University Hospital Brno (104 T1-weighted MR images of subjects, of which 52 subjects were patients with first episode

of schizophrenia (FES) and 52 were healthy volunteers (HC)). Classification performance was evaluated using leave-one-out cross-validation. The best results of experiments with differently selected parameters are shown in Table 1.

Table 1. Classification accuracy for distinguishing between FES and HC.

Morphometric method	Metrics	Decomposition level	Number of features	Accuracy [%]	Sensitivity [%]	Specificity [%]
DBM	FDR	4	1000	56.73	55.77	57.69
			5000	69.23	67.31	71.15
		5	1000	58.65	57.69	59.62
			5000	72.12	67.31	76.92
	Var	4	1000	57.69	55.77	59.62
			5000	69.23	67.31	71.15
		5	1000	59.62	57.69	61.54
			5000	71.15	67.31	75.00
VBM	FDR	4	1000	73.08	71.15	75.00
			5000	67.31	65.38	69.23
		5	1000	71.15	69.23	73.08
			5000	67.31	63.46	71.15
	Var	4	1000	73.08	71.15	75.00
			5000	69.23	67.31	71.15
		5	1000	71.15	69.23	73.08
			5000	68.27	65.38	71.15

2. Discussion and conclusion

The strongest results were obtained using DBM, where the classifier achieved the best performance for five decomposition levels selected using FDR and Var for 5000 features. The first case achieved 72.12% accuracy, 67.31% sensitivity and 76.92% specificity, and the second case attained 71.15% accuracy, 67.31% sensitivity and 75.00% specificity. Using VBM with four decomposition levels for 1000 features and Var. and FDR metrics, 73.08% accuracy, 71.15% sensitivity, and 75.00% specificity were achieved.

The results from this analysis are comparable to those of similar works [4], [5], [6]. Despite the classification of FES and HC, the resulting accuracy is still too low to propose the algorithm be used in clinical practice as an objective method for the diagnosis of this devastating neuropsychiatric disorder. This work was supported by the project No. AZV 17-33136A (Ministry of Health, CZ).

Classification of Histologic Images Using a Single Staining: Experiments with Deep Learning on Deconvolved Images

Vincenzo DELLA MEA^{a,1} and David PILUTTI^a

^a*Dept. Of Mathematics, Computer Science and Physics, University of Udine, Italy*

Abstract. The automated analysis of digitized immunohistochemistry microscope slides is usually a challenging task, because markers should be analysed on the tumor area only. Tumor areas could be recognized on a different slide, stained with Haematoxylin-Eosin. The basic idea of the present poster is to evaluate how well deep learning methods perform on the single haematoxylin component of staining, with the prospective possibility of developing a classifier able to recognize tumor areas on IHC slides on their haematoxylin component only. In a preliminary experiment, single stain images obtained by H-E color deconvolution showed an accuracy of 0.808 and 0.812 for Hematoxilyn and Eosin components, respectively.

Keywords. Deep Learning, Digital slides, cancer

1. Introduction

The automated analysis of digitized immunohistochemistry (IHC) microscope slides is an actual and challenging problem, because markers should be analysed on the tumor area only. The IHC samples are stained with diaminobenzidine (DAB) to reveal a specific biological marker, and counterstained with Haematoxylin (H) to identify the cellular context. Tumor areas could be recognized on a different slide, stained with Haematoxylin Eosin (H-E). This normally raises the complexity of an automated analysis, introducing new tasks such as the alignment of the differently counterstained samples. In the last years, however, notable results have been obtained in tumor and metastases detection on H-E stained digital slides using deep learning techniques [1,2].

The basic idea of the present poster is to evaluate how well deep learning methods perform on the single stainings, with the prospective possibility of developing a classifier able to recognize tumor areas on IHC slides on their H component only. A preliminary experiment has been made on H-E stained images coming from the Bach Challenge [2].

2. Methods

The dataset for the classification tasks comes from the BACH Challenge [2], Part A. It consists of training (n=400) histologic images from breast cancer, acquired at 0.42µm

¹ Corresponding Author, Vincenzo Della Mea, Dept. Of Mathematics, Computer Science and Physics, University of Udine, via delle Scienze 206 – 33100 Udine Italy E-mail: vincenzo.dellamea@uniud.it.

and labelled with 4 categories, imagewise (normal, benign, in-situ carcinoma, invasive carcinoma). As a baseline, a model has been trained on the original, full color images, split into 1024x1024 tiles with a 128 pixels stride, using Fastai as programming framework [3]. Images were then transformed into their H and E components, using the Color Deconvolution plugin of ImageJ [4] with its standard H-E vectors.

The same model has been trained separately on the two staining components, after RGB conversion to make them compatible with the model. Accuracy evaluation has been carried out with the Bach Challenge rules [2].

3. Results

The baseline model was based on ResNet152, pretrained on Imagenet on 3 epochs on the last layer, plus 3 epochs for fine tuning on the whole network. The model achieved almost state-of-the-art accuracy (average of 0.845 on 4 runs, with a maximum of 0.88). The Haematoxylin model reached an average accuracy of 0.8075 on 4 runs (maximum: 0.84), while the eosin model reached 0.812 (maximum: 0.83).

4. Discussion

The models trained on single staining images obtained an accuracy lower than the full image one, although, if compared with the challenge results, they could still rank among the best 10 [2]. This result has been obtained without any specific optimization for these images, as the model architecture and hyperparameters of the baseline model have been fully replicated. Furthermore, no custom deconvolution vectors could have been computed, and this could have lowered the classification performance.

Further work includes running the experiment on images acquired in a controlled environment, to compute the deconvolution vectors. Furthermore, classification of deconvolved H-DAB images in their Haematoxylin component will be also considered to prove a cancer recognition method for IHC in alternative to image registration

5. Acknowledgements

Classification of Normal and Cardiomegaly Conditions in Chest Radiographs Using Cardio-Mediastinal Features

Satyavratn GOVINDARAJAN¹, Sukanta Kumar TULO and Ramakrishnan SWAMINATHAN

*Non-Invasive Imaging and Diagnostics Laboratory, Department of Applied Mechanics
Indian Institute of Technology Madras, Chennai, India - 600036*

Abstract. In this study, an attempt has been made to differentiate normal and cardiomegaly using cardio-mediastinal radiometric features and machine learning approaches. A total of 60 chest radiographs including normal and cardiomegaly subjects are considered from a public dataset. The images are preprocessed using edge aware contrast enhancement technique to improve the edge contrast of lung boundaries. The mediastinal, cardiac and thoracic widths and their radiometric indices are computed to characterize the morphological variations. The features are fed to three different classifiers for the differentiation of normal and cardiomegaly. Results show that the Linear discriminant analysis classifier is found to perform better with average values of recall 88.7%, precision 88.8%, and area under the curve 91.9%. Hence, the proposed computer aided diagnostic approach appears to be clinically significant to distinguish normal and cardiomegaly especially in remote and resource - poor settings.

Keywords. Cardiomegaly, Cardio-Mediastinal features, Machine learning

1. Introduction

Cardiomegaly is a medical condition that affects the cardiovascular system, specifically involving the enlargement of heart. This signature results from hosts of other diseases and strongly associated with congestive heart failure. Mediastinum region in the chest is considered as one of the substantial anatomical regions for the gross diagnosis of cardiovascular abnormalities. Early detection with mass screening approaches are crucial to prevent such condition, particularly in remote and resource-poor settings. Chest radiographs (CXRs) have been widely used for this purpose due to their non-invasiveness, and portability. Conventional image processing methods applied on CXRs fail to characterize the condition and differentiate them from normal subjects.

2. Methods

The frontal CXRs of 60 subjects (Normal- 30, Cardiomegaly-30) are obtained from Chest X-ray14 publicly available dataset. The images are in grayscale with a resolution

¹ Satyavratn Govindarajan, Non-Invasive Imaging and Diagnostics Laboratory, Department of Applied Mechanics, Indian Institute of Technology Madras, Chennai, India - 600036; E-mail: s.vratan@gmail.com.

of 1024*1024. The images are subjected to edge aware contrast enhancement technique. It is used to enhance the contrast in smaller sub-regions of the image by retaining the edge information [1]. This method uses local Laplacian filtering based on Gaussian to distinguish edges from details. Sharpness measure is used to validate the edge contrast enhancement of lung boundaries.

Left mediastinal width and mediastinal width [2], cardiac width and thoracic width features are extracted, and their corresponding ratiometric indices such as Mediastinal width ratio, Cardiothoracic ratio [3], Mediastinal cardiac ratio (Mcr) and Mediastinal thoracic ratio are derived for all the subjects. All the features are provided to Linear Discriminant Analysis (LDA), Naïve Bayes (NB) and Support Vector Machine (SVM) classifiers. Ten-fold cross validation is performed and the performance measures are evaluated.

3. Results and Discussion

Figure 1. Representative images (a) normal and cardiomegaly (b) preprocessed (c) Mcr plot

From Figure 1, it is seen that the original images have poor edge contrast especially along lung boundaries at significant anatomical landmarks and the adopted preprocessing method is found to enhance the edge contrast locally. Significant distinction is observed between normal (0.3-0.55) and cardiomegaly (0.28-0.42) using Mcr plot.

The performance comparison of classifiers is shown in table 1. It is found that LDA performs better than NB and SVM with average values greater than 88% for recall, precision and F-measure and AUC of 91.9%. Large number of input images would be considered for future work.

Table 1. Performance of classifiers using all the features

Classifiers	Recall (%)	Precision (%)	F-measure (%)	AUC (%)
LDA	88.7	88.8	88.7	91.9
NB	82.3	82.4	82.4	88.4
SVM	85.5	85.5	85.5	86.0

¹ Sorbonne Université, INSERM, Université Paris 13, Laboratoire d'Informatique Médicale et d'Ingénierie des Connaissances en e-Santé, Paris, France.

² EISTI, International Engineering School, 95000 Cergy-Pontoise, France

³ Centre Régional de Pharmacovigilance, Hôpital Européen Georges-Pompidou, Assistance Publique – Hôpitaux de Paris, Paris, France.

Abstract. This poster presents a non-exhaustive study of machine learning classification algorithms on pharmacovigilance data. In this study, we have taken into account the patient's clinical data such as medical history, medications taken and their indications for prescriptions, and the observed side effects. From these elements we determine whether the patient case is considered serious or not. We show the performances of the different algorithms by their precision, recall and accuracy as well as their learning curves.

Keywords: Classification, Machine Learning, Pharmacovigilance, Decision support tool.

1. Introduction

Since 2017 in France, citizens can report directly to health authorities any adverse event related to health products. The objective of the presented work is to study to which extend machine learning algorithms could predict the seriousness of the situation from the description of the situation by patients. We used structured data recorded by health professionals from the verbatim of the patient to train machine learning algorithms. The main perspective is to apply the resulting prediction system to social media for pharmacovigilance monitoring. Although, signal detection in pharmacovigilance is historically based on statistical methods, more and more machine learning can make predictions for the detection of side effects [1]. Andrew M Wilson in [2] concluded that machine learning will not replace traditional pharmacovigilance technics but could collaborate to detect uncommon drug-related effects or reducing adverse drugs effects identification time.

2. Methods and Results

To carry out the study we considered a database that includes all the cases reported by patients from 2010 to 2019 resulting in a base of 13026 patient cases described by 50 variables from HEGP (European Hospital Georges Pompidou), Paris, France. Cases reported in this database are standardized by pharmacovigilant using MedDRA terms. 8699 cases are annotated as serious by health professionals. The aim of the study is to search the most efficient supervised learning algorithm that will enable the pharmacovigilant to prioritize serious cases. In a first step, all values of a variable are considered as a bag of word and translated in terms of presence/absence ("one-hot-encoding"). This operation allows to keep the inter-variable interaction for poly-medical or poly-pathological patients.

Before applying an algorithm, the dataset is divided in two, 75% of the database will serve as a training base and 25% will be used to test the learning performance. This process is repeated 5 times in order to have a general tendency of the performances of the different methods. Then we apply 9 different state-of-art clustering models to our dataset thanks to available libraries: *Decision Tree*, *Bagging Tree*, *Boosting Tree (AdaBoost)*, *Gradient Boosting Machine*, *K-Nearest Neighbours (K-NN)*, *Logistic Regression*, *Neural Network*, *Random Forest*, *Support Vector Machine (SVM)*. The next figure left shows the results in terms of precision (proportion of good prediction if the case is severe) and recall (percentage of serious cases correctly identified). The model with the best performance in terms of accuracy and recall is the logistic regression (next figure right). It does not over-fit the data and is very accurate (cf. LR learning curves next figure right).

3. Discussions and conclusion

It is important to note that the performance of machine learning methods depends on the input data that is used for learning. The same method on a different data set will give different results. Similarly, as new several observations are saved to the database, the performance of the same method will change over time. During this first study, it was decided to work initially with the default values of the algorithms because we did not have a priori knowledge to force the value of certain parameters. One possible improvement will be to choose optimal settings for all models and re-compare their performances later. For that we could use a search grid where all the parameters would be stored and build the models that would test all the possible combinations to determine the best of all.

Coping with IT Downtime in Hospitals

Jackline BAMDEG^a and Thomas SCHMIDT^{a, 1}

^a*The Maersk Mc-Kinney Moller Institute, University of Southern Denmark*

Abstract. Downtime of information systems is a universal challenge faced by health care institutions. In this poster, we present the findings of a scoping review of how hospital organizations and their staff deal with downtime, and how coping can be grouped into three strategies; 1) Increasing communication, 2) Analog fallback, and 3) Restricted redundant systems. Our findings point to the importance of customizing coping mechanisms for individual healthcare institutions, and designing systems that empower users to deal with downtime.

Keywords. Health Information Systems, Downtime, Coping, Failure

1. Introduction

Anecdotal stories about system breakdowns and information technology (IT) downtime are frequent in health care. More rigorous investigations into the incidence of downtime has found that almost all healthcare institutions have experienced at least one unplanned downtime event, and that for the majority of these events the duration exceeded eight hours. Despite contingency planning and strategies for downtime handling, organizations still struggle to ensure that end-users of IT react sensibly during prolonged incidents. The aim of this work is to present an overview of coping mechanisms for handling unexpected downtime in hospitals. We focus on systems that can be fully, or partially, substituted with improvised solutions during the episodes.

2. Method

The study was conducted as a scoping review based on the search phrase ("technology failure" OR downtime) AND ("electronic health record" OR EHR OR "Information system" OR "electronic medical record" OR "Patient administration system" OR Paperless OR "Emergency care information systems" OR "Hospital Information Systems"). We searched Pubmed, Engineering Village, and Cinahl. Included papers was thematically analyzed to identify general coping categories.

3. Results

A total of 51 studies were assessed in full text, resulting in the inclusion of 13 studies for the final analysis. From the thematic analysis we structured the coping mechanisms

¹ Corresponding Author, Thomas Schmidt, Centre for Health Informatics and Technology, University of Southern Denmark, Campusvej 55, DK-5230 Odense M, Denmark.; E-mail: schmidt@mmmi.sdu.dk

into three categories: 1) *Increased communication* which sought to facilitate the lack of coordination offered by the IT system, 2) *Analog fallback* to capture the clinical information and knowledge needed for processing and treatment of patients in alternate ways, and 3) *Restricted redundant fallback* systems which still utilized IT but without access to the entire suite of functionality. The findings of our analysis are distilled into Table 1.

Table 1. Overview of results

Category	Coping mechanism	Affected system	Cause
Increased communication	Phone , Alternative working procedures, Email, Command center, Mass communication, Designated mediators	EHR, CPOE, LIS, HIS	System upgrade System launch, Hardware failure, Cyber-attack
Analog fallback	Printed labels, White board, Supplementary Paper Forms, Notebooks, Emergency Toolkit, Printed Ad-hoc logs	EHR, CPOE, CDSS, LIS, HIS	System upgrade, System launch, Hardware failure, Cyber-attack Natural disaster
Restricted redundant systems	Use of offline computers, Read-only systems	EHR, Medication administration	Hardware failure

The majority of downtime cases involve Electronic Health Records (EHR) or Hospital Information Systems (HIS), but also order entry systems (CPOE), clinical decision support (CDSS), and laboratory systems (LIS) were implicated. The coping mechanisms were coupled to the type of system affected.

4. Discussion

Given the steady improvement of hard- and software technology, one might expect that the risk of downtime would diminish over time, or even be an outdated issue. Yet, as illustrated by anecdotes as well as literature, this is not the case. During breakdowns, organizations either resolve to utilize broadcasting of information, or appointing designated carriers of information. Fallback systems are either improvised or designed in advance. In some cases, institutions were aware of the growing disparity between electronic or paper-based documentation and consequently prepared an entire emergency toolkit. From our initial navigation of the field, it is evident that grey literature of all kinds actually include a richer source of cases and experience. Given enough time and resources, there is most likely a lot of learning to be distilled from a systematic approach to collection and analysis of these stories.

5. Conclusion

The three coping strategies identified in this review, and the frequency by which they have been utilized, are indicative of the continued need for having fallback systems in place to handle lack of access to the IT systems. Although there are a number of research instruments available for gauging the impact of downtime, there is a need to harvest the experiences described in grey literature.

Creating and Implementing a Professional Development Program to Improve Organizational Capacity for Health Analytics in a Public Health Setting

^a*Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina.*

Abstract. The implementation of an Electronic Medical Record (EMR) in the public healthcare system of Buenos Aires City began in June 2016. AGISE is a government department that assists in health decision-making processes by providing timely and quality data. In this study we designed a professional development program to improve organizational capacities for health analytics.

Keywords. professional development, training program, health analytics.

1. Introduction

The implementation of an Electronic Medical Record (EMR) in the public healthcare system of Buenos Aires City began in June 2016 as a central component of a Health Information System. The management of the large amounts of data that it generates is a complex, interesting, and vital challenge for the sustainability and development of this system and organization.

AGISE is a government department within the Health Ministry of the city of Buenos Aires, whose objective is to assist in health decision-making processes by providing timely and quality data to people of all decision levels. Through qualified professionals with heterogeneous profiles, AGISE aims to form a multidisciplinary work team within the public health sector. Current challenges in achieving this include finding new people who are able to adapt to desired profiles, identifying any gaps between the experience of the potential hires and the needs of the organization, and the difficulties in competing with the labor market due to less competitive salary usually offered by government institutions. The aim of this study is to describe the design and implementation of a comprehensive development program including a training curriculum for new members of the team and a continuous training program for the stable staff; to encourage a dynamic and collaborative analytical community in the public health sector in the context of new information and communication technologies (ICT).

¹ Corresponding author. E-mail: maizpurua@buenosaires.gob.ar.

2. Methods

The design of a competency-based educational program began with a review of the literature to rely on the best practices in professional development programs[1][2]. Expected analytic profiles were defined, with roles and tasks to be assigned. Training needs were assessed through semi-structured interviews with team members. As a result and according to the organization's mission, general and individual training and developmental goals were defined following the SMART criteria (Specific, Measurable, Achievable, Realistic, Timely). Transferable experience, skills and available resources were identified and analyzed to find out what the team was lacking. An action plan and timeline were developed, and its execution began in June 2019. Evaluation tools were designed to assess our progress and revise accordingly.

3. Results

The chosen training methodology is focused on competencies, with distributed learning following the principles of participation, repetition, relevance, transfer and feedback [3][4]. We selected priority contents for the curriculum of new members and organized them in an intensive two-week self-administrable package. For the continuous training of the stable team, we selected contents and organized them into seven thematic units distributed in an annual schedule. Small group projects, talks with experts, hands on workshops, theoretical classes, book clubs, and virtual courses were some of the modalities applied. For each thematic unit the programmed activities were scheduled in a shared calendar, their materials and resources stored in an accessible and indexed repository, and a forum was created to share questions, doubts, and experiences. We developed tools for both, evaluation and monitoring, to make it possible to adapt and optimize the curriculum's contents, as well as consider including new topics.

4. Conclusion

The implementation of a professional development plan that guides the initial training of new members and the continuous training of the team is a vital resource for the growth and development of organizations. Monitoring is necessary to assess progress and review accordingly.

Cross-Mapping Study of Nursing Practice Terms from a Brazilian Hospital Database

Luciana Schleder GONÇALVES^{a,1} Dayane ANDREATTA^b and Fernanda Karoline SCHAMNE^c

^a*Nursing Undergraduate and Graduate Program Professor, UFPR, Brazil*

^b*Nursing Undergraduate Program Student, UFPR, Brazil*

^c*Master in Nursing Science Program Student, UFPR, Brazil*

Abstract. Objective: To perform a cross-mapping study between nursing documentation from a Electronic Health Record (EHR) of a Brazilian hospital and four nursing terminology systems. Method: Descriptive, quantitative and retrospective study. Results: The EHR presents a total of 247 anamnesis / physical examination terms, 75 nursing diagnoses, and 205 nursing interventions terms to nurses make their choice. Conclusion: Authors strongly recommend that attempts in building more usable and friendly EHRs for clinical care practice documentation consider classification systems structures in their development, to ensure complete, safe, evidence-based and comparable registries.

Keywords. Nursing documentation. Nursing Informatics. Electronic Health Record. Terminologies. Cross-mapping.

1. Introduction

The Nursing Process (NP) is composed of interrelated steps that provide quality to nurse's clinical thinking and enable continuity of care in healthcare settings [1]. Anamnesis and physical examination data are gathered in its first stage and are essential to measure the resolution of care [2]. Nursing diagnosis (ND) is a clinical judgment about problems of an individual, family or community, over which nurses can intervene favoring their quality of life. This judgment is based on the nurse's assessment of the history, complaints, social and physiological data of the patient to whom nursing care is being delivered [3]. Nursing interventions (NI) are sets of actions that coordinate the "doing" of nursing care, and should be based on observation and evaluation of problems presented by the individual, family or community [1].

¹ Corresponding Author, Address: Rua Lothario Meissner, 632 Bloco Didático II, Departamento de Enfermagem, UFPR. Curitiba-PR-Brazil. E-mail: lualevale@gmail.com

In order to organize the specific language of nursing, classification systems have emerged, which allow the unification of concepts relevant to this area, considering their wide scope and performance in the fields of teaching, management, research and care [3].

2. Method

In order to cross-map anamnesis and physical examination, diagnoses and nursing interventions terms available in the hospital's EHR with four nursing standardized classification systems, a descriptive and retrospective study of quantitative approach was performed.

This study is part of a project entitled 'Artificial Intelligence and the management of sepsis patients: its influence on decision making, nursing interventions and outcomes', approved by the Health Sciences Sector of the Federal University of Paraná (UFPR, Brazil) Institutional Review Board (IRB) in May 2018, under registration number 84602218.8.0000.0102 and approved by the the co-participating IRB under registration number 84602218.8.3001.0098.

3. Results

From the EHR list of options, 247 terms referred to the description of anamnesis and physical examination, 75 to ND and 205 to NI. The match rates range from 58% to 100%, depending on the stage of the nursing process and the classification system mapped.

4. Conclusions

Care documentation is a challenge in current healthcare practice - it is a major cause of burnout among clinicians and nurses, and it is also mandatory for the continuity of care, visibility of nursing profession contribution and for legal and billing matters.

In this study a cross-mapping experiment is presented which reflects the importance of translational research in health and nursing informatics. Scientific knowledge, here presented by robust classification systems, provide the foundation for data, information, knowledge and wisdom structures that contribute to highlight clinical reasoning and evidence of healthcare practices. Authors strongly recommend that attempts in building more usable and friendly EHRs for clinical care practice documentation consider these structures in the development, to ensure complete, safe, evidence-based and comparable registries.

Data Integration Approaches for Representing Stem Cell Studies

Irena PARVANOV^a and Joseph FINKELSTEIN^{1a}

^a*Icahn School of Medicine at Mount Sinai, New York, NY, USA*

Abstract. The aim of this study was to examine existing methods for sharing results of stem cell research via online data repositories. To identify the relevant repositories, a PubMed search was conducted using standard MeSH terms which was followed by a web-based search of relevant databases. The search yielded 16 databases created between 2010 and 2019. The review of databases identified 35 major rubrics and their sub-rubrics organized in a five-module system. Data integration approaches were characterized by three domains (common data elements, data visualization and analysis tools, and ontology mapping) which varied widely across the databases. Current state of stem cell data integration lacks reproducibility and standardization. Standardization of data integration approaches for representing stem cell studies is necessary to facilitate data sharing.

Keywords. Data integration, data sharing, stem cells, standardization

1. Introduction

An exponential expansion of stem cell research results in voluminous data set aggregation [1]. However, effective approaches for intelligent integration and sharing of these resources have not been established. The aim of this study was to examine existing methods for sharing results of stem cell research via online data repositories.

2. Methods

Stem cell repositories were identified by using “Databases, Factual AND Stem Cells” MeSH terms in PubMed and web search for stem cells databases created between 2010 and 2019. All identified databases were manually reviewed and characterized.

3. Results

Overall, we located 14 academic databases indexed in PubMed and two databases not reflected in peer-reviewed literature (Table 1). The databases varied widely in data elements, analysis tools, search functionality and update methodology. Their features were summarized in 35 rubrics including names, lineage, surface markers, transcription factors as well as types of detection assays and clinical trial information.

¹ Corresponding author: Email: Joseph.Finkelstein@mountsinai.org.

Diverse rubrics were organized into a five module system based on Minimal Information About a Cellular Assay for Regenerative Medicine (MIACARM) [2] including Project, Assay, Source cell, Experimental technology, and Data.

4. Discussion

Data integration approaches were characterized by three domains (common data elements, data visualization and analysis tools, and ontology mapping) which varied widely across the databases. Current state of stem cell data integration lacks reproducibility and standardization. Standardization of data integration approaches for representing stem cell studies is necessary to facilitate data sharing. Consensus on common data elements and data exchange standards will facilitate data integration approaches in stem cell-based research and promote research transparency and reproducibility.

Data Provenance Standards and Recommendations for FAIR Data

Malte-Levin JAUER^{a,1} and Thomas M. DESERNO^a

^a*Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and
Hannover Medical School, Braunschweig, Germany*

Abstract. This article reviews the main characteristics of five widely used data provenance models and recommendations. We suggest a set of six provenance properties that should be satisfied by any provenance model as a basis for further implementation of provenance mechanisms, supporting the findable, accessible, interoperable and reusable (FAIR) principles for both, research and health data.

Keywords. Data provenance, FAIR data, Metadata, Research data, Health data

1. Introduction

In health research, data capture and data quality varies strongly. Therefore, information on data provenance is needed along the whole processing pipeline [1]. This includes the generation of persistent identifiers (PIDs) to make the data findable and accessible and is crucial to reuse data. Therefore, providing data provenance information is a mandatory step towards findable, accessible, interoperable and reusable (FAIR) data [2].

2. Methods

We consider five provenance standards identified within the FAIR4Health project [3]. A widely used provenance model is the W3C PROV-DM data model [4]: an acyclic directed graph, consisting of nodes “entity”, “activity”, and “agent”. Recommending specific provenance items, the DataCite International Consortium developed a metadata scheme in 2009 [5]. It stresses assignment of digital object identifiers (DOIs) and includes six domain-agnostic mandatory properties. In 2016, a domain-specific extension to the DataCite metadata schema for health was presented: the ECRIN Clinical Research Metadata Schema [6]. It includes information on the source study, associated consent and access details. The Research Data Alliance endorsed 14 recommendations of the Working Group Data Citation (WGDC) [7] targeting reproducibility of data used in experiments and studies. Therefore, persistent identifiers have to be generated in a query-based manner, so that data views can be cited and retrieved by re-executing the query. As a result of the Data Quality Collaborative (DQC), Kahn et al. [8] proposed 20 data quality and provenance recommendations. They especially highlight that each transformation of the source data has to be documented, including data cleansing values.

¹ Corresponding Author: Malte-Levin Jauer, Peter L. Reichertz Institute for Medical Informatics, Mühlenpfordtstr. 23, 38106 Braunschweig, Germany; E-mail: malte-levin.jauer@plri.de.

3. Results

We extracted the following list as minimal “fit for use” requirements for provenance model (Table 1). Check-marks indicate, which recommendation(s) support these items.

Table 1. Comparison of the different provenance recommendation sets.

Criteria	DataCite	ECRIN	WGDC	DQC
<i>Persistent identifier (PID)</i> : Each data object is assigned a unique, persistently stored identifier. Ideally, a DOI is assigned.	✓	✓	✓	✗
<i>Data origin</i> : The project or event that generated the data.	✓	✓	✗	✓
<i>Data creator</i> : A person or institution to be credited for.	✓	✓	✗	✓
<i>Data timestamp</i> : The time of dataset creation/modification.	✓	✓	✓	✗
<i>Data versioning</i> : Each transformation result of the data object is stored. Earlier versions are retrievable.	✓	✓	✓	✓
<i>Query PID</i> : If (sub-)sets of data are generated or cited, the query is stored with a persistent ID for reproducibility.	✗	✗	✓	✓

4. Discussion

The present work has identified six minimal criteria from the given provenance overview, implementable using the PROV-DM data model. The feasibility of these items will be investigated in the FAIR4Health project’s demonstrators.

Data Visualisation in Midwifery: The Challenge of Seeing what Datasets Hide

Bridget J DALEY^{a,1}, Evangelia KYRIMI^b, Kudakwashe DUBE^{c,d}, Norman E FENTON^b, Graham A HITMAN^a, and Scott MCLACHLAN^{b,d}

^a*Genomics and Child Health, Blizard Institute, Queen Mary University of London (UK)*

^c*School of Fundamental Sciences, Massey University (NZ)*

^d*Health informatics and Knowledge Engineering Group (HiKER)*

Abstract. Information visualisation is transforming data into visual representations to convey information hidden within large datasets. Information visualisation in medicine is underdeveloped. In midwifery, the impact of different graphs on clinicians' and patients' understanding is not well understood. We investigate this gap and its potential consequences.

Keywords. data visualisation, midwifery

1. Introduction

Data visualisation is transforming data, information and knowledge into visual representations that convey meaningful patterns and trends hidden within large datasets [1]. Ineffective data visualisation negatively impacts clinical care and patient safety [2]. Effective visualisation mitigates comprehension, interpretability and data navigation issues [3]. Data visualisation in clinical medicine is underdeveloped [4]. This is especially true for midwifery. Finding appropriate ways to visualise data is challenging [5], and depends on objectives, context and audience [5]. Studies confirm the effectiveness of data visualisation. This paper investigates how data visualisation could be better applied in midwifery.

2. Method

A multi-database search was conducted using the terms “data visualisation” and “midwifery”. Duplicates, irrelevant papers and those which spoke of data visualisation but failed to present any form data visualisation in were removed. This resulted in a collection of just 10 papers for use in this review.

¹ Corresponding Author, E-mail: b.j.daley@qmul.ac.uk

3. Results

Our review identified that midwifery uses extremely limited and primitive data visualisation methods. Bar charts [6] and line graphs [7] dominated, with only one work [8] using any graphical representation. No works addressed visualisation methods for midwifery. Midwives are not being exposed to approaches that could improve their understanding and assimilation of clinical data, and accordingly lack awareness of approaches to and benefits of data visualisation.

4. Discussion

Direct patient care will continue to be the driving concern, but how midwives engage with patient data and research must evolve in the era of big data [9, 10]. Many consider data science as the next evolution for midwifery, yet few midwives understand what data visualisation is and the impact it may have [9, 10]. Increasingly, effective information visualisation may hold the key to understanding complex data in electronic health record datasets. Midwives must embrace data visualisation and the knowledge it can convey.

5. Conclusion

We have investigated the use of data visualisation within the domain of midwifery. Research is needed to assist midwives who work with or present data to do so using appropriate data visualisation. Without this, midwives will continue to be constrained by the challenge of seeing what datasets hide.

Deep Learning Approach for the Development of a Novel Predictive Model for Prostate Cancer

Mohaimenul ISLAM^{a,b}, Hsuan-Chia YANG^{a,b}, Phung-Anh NGUYEN^{a,b}, Yu-Hsiang WANG^{a,b}, Tahmina Nasrin POLY^{a,b}, Yu-Chuan (Jack) LI^{1a,b}

^a*Graduate Institute of Biomedical Informatics, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan.*

^b*International Center for Health Information Technology, Taipei Medical University, Taipei, Taiwan.*

Abstract: We developed a deep learning approach for accurate prediction of PCA patients one year earlier with minimal features from electronic health records. The area under the receiver operating curve for prediction of PCA was 0.94. Moreover, the sensitivity and specificity of CNN were 0.87 and 0.88, respectively.

Keywords: Prostate cancer, deep learning, convolutional neural network, electronic health record.

1. Introduction

Prostate cancer (PCA) is the most commonly diagnosed cancer in men and the fifth leading cause of death globally [1]. Earlier stratification of patients at high risk of PCA offers an immense potential to decrease morbidity and mortality. Prostate-specific antigen (PSA), however, is a widely used and reliable test that is currently applied in screening the patients for correct identification of PCA patients. We, therefore, developed a novel prediction model using CNN algorithm with minimal features from HER that may help to stratify high-risk patients before a diagnosis of PCA. To our knowledge, it is the first study to develop a prediction model of identifying PCA patients one year earlier.

2. Methods

Two million population data between January 01, 1999 and December 31, 2013 was randomly selected to conduct this current study. All the patients who were ≥ 20 years old and diagnosed with prostate cancer retrieved from the database between January 01, 1999 and December 31, 2013. PCA patients were confirmed by using ICD-9 codes and record in the Registry of Catastrophic Illness Patient (RCIP), a subpart of the NHI database.

¹ Corresponding author Email: jaak88@gmail.com / jack@tmu.edu.tw

Patient to be included in the RCIP database must have pathological confirmation and treatment history of PCA. We then checked the total number of prescription and length of prescription for those patients. Afterwards, 7-days clinical information of all patients was summed up continuously. A total of 157 grid was constituted of 1095-days patients' information. We developed CNN model with a 5- fold cross-validation technique in this study. The area under the receiver operating curve, Sensitivity, specificity was used to measure the performance of our model.

3. Results

A total of 4,071 PCA and 16,284 controls were included in our current study. The mean age of case and control patients were 70.0, and 47.5 years, respectively. All the patients diagnosed with PCA were male. The average number of diagnosis in patients with PCA were higher than controls (44 vs 24) when we considered PCA and non-PCA patients one year before index date. However, over the three years, the average number of diagnosis in PCA and non-PCA patients was 41.23 and 22.66. The mean of AUC of the CNN model in the minimal electronic health record feature was 0.94, with sensitivity of 0.87 and specificity of 0.88 at the threshold value of 0.4.

4. Discussion & Conclusion:

In this current study, we focused on predicting PCA patients one year ahead from the minimal feature of electronic health records by the widely used CNN model. However, the CNN approach has shown high sensitivity and specificity for predicting PCA with the minimal feature of EHR. Based on these current findings, it is obvious that deep learning prediction model could provide physicians immense opportunity to improve patient outcomes through earlier PCA identification and subsequent follow-up high-risk PCA patients. Having provided timely treatment to patients may help to improve survival rate, minimize treatment costs and reduce risk of mortality [2]. We developed a novel deep learning risk prediction model for the prediction of PCA with minimal features of EHR. Our model, which includes patient demographics, comorbidities, co-medications, can be used to identify patients at high risk of PCA one year earlier.

^c*Instituto de Salud Carlos III, Spain.*

Abstract. This work aims to define a standardized information model for representation of multiple data sources in breast cancer. A set of data elements has been identified using ICHOM Breast Cancer as the minimum data set and adapting it to the needs of Hospital Universitario 12 de Octubre. With this, an information model has been defined according to ISO 13606 and SNOMED CT standards.

Keywords, EHR, Information model, Standardization, Breast cancer, ISO 13606, SNOMED-CT, ICHOM.

1. Introduction

Advanced uses of health information require standard data that allows its representation without loss of meaning [1], essential in a multidisciplinary condition such as breast cancer. This work aims to define an information model for the standardized representation of data in breast cancer domain.

2. Methods

First, the set of data elements for breast cancer domain was identified using ICHOM Breast Cancer [2] as the minimum data set. Second, this data set has been reviewed and adapted to the needs of Hospital Universitario 12 de Octubre [3]. Finally, based on this specification, an information model has been defined according to ISO 13606 [4] and SNOMED CT [5].

3. Results

Table 1 shows the number of data elements that have been identified, comparing them with the number of elements defined by ICHOM Breast Cancer.

Table 1. Data elements identified by categories and compared with ICHOM Breast Cancer

Data category	ICHOM BC	Data Element Set
Clinical	47	71
Pathological Anatomy	17	84
PROM	104	104
Total	168	259

Table 2 shows an example of standardized data element using the reference model of ISO 13606 and SNOMED CT.

Table 2. Data element standardized according to ISO 13606 and SNOMED CT standards

Component	Data-type	Cardinality	SCT Code	SCT Term
Element	Coded Value	1	371480007	Tumor site
Value	-	-	181134008	Entire upper outer quadrant of breast
Value	-	-	181136005	Entire lower outer quadrant of breast
Value	-	-	181132007	Entire upper inner quadrant of breast
Value	-	-	181135009	Entire lower inner quadrant of breast
Value	-	-	205042000	Entire central portion of breast
Value	-	-	265780004	Entire nipple

4. Conclusions

Data set proposed by ICHOM Breast Cancer has been used as the minimum data set. It has been necessary to increase the number of data elements from 168 to 259 to adapt it to the needs of the Hospital (see Table 1).

The combined use of ISO 13606 and SNOMED CT has allowed the standardized definition, structure and meaning, of previously identified data elements. This will allow advanced uses of these data with full meaning.

Acknowledgment

This work has been elaborated within the Research Projects PI15/00321, PI18/00981 and PI18CIII/00019, funded by Instituto de Salud Carlos III.

Design of a Supportive Transfer Robot System for Caregivers to Reduce Physical Strain During Nursing Activities

Christian KOWALSKI ^{a,1}, Pedro ARIZPE-GOMEZ ^a, Conrad FIFELSKI ^b,
Anna BRINKMANN ^b and Andreas HEIN ^b

^aOFFIS Institute for Information Technology, Oldenburg, Germany

^bCarl von Ossietzky University Oldenburg, Oldenburg, Germany

Abstract. The number of people in need of long-term care is rising and personnel scarcity is already foreseeable. The shortage of caregivers is further increased due to early retirement attributed to the major health burden when working at high speed with heavy lifting. Since nursing staff in many cases work beyond their physical strain limits during routine activities at the bed and existing systems do not counteract the current trend, we investigate with the present work whether the concept of a collaborative robotic support system can contribute to the physical relief of the nursing staff to make it possible to fall below the physical strain limits.

Keywords. robotics, human-robot collaboration, computer vision, camera calibration

1. Introduction

As the worldwide population is aging, the demand for caregiving personnel is increasing. In addition to this shortage of qualified personnel, the problem of physical overload, which results mainly from the high working speed and heavy lifting, prevails within the health care system. This overload in turn leads to an inability to work or an early retirement of the personnel [1], thus resulting in an even greater shortage of available staff. The biomechanical overload during routine nursing activities has been previously measured and described in detail [2]. In that work, the compressive force on the lumbosacral disc of the spine of caregivers during the execution of nine different types of nursing activities (e.g. moving the patient to the bed's head end) was estimated using a biomechanical model. In most cases, the estimated lumbar load values are not within acceptable limits. Consequently, technologies to reduce the physical load must be developed. While conventional support systems, such as patient lifts, have the drawbacks of slow patient transfer and limited usability, robotic solutions may have the potential to cooperatively support the nurse during physically demanding activities. In this work, we focus on the research of such a system in order to identify its limits.

¹Corresponding Author: Christian Kowalski, OFFIS Institute for Information Technology, Escherweg 2, 26121 Oldenburg, Germany; E-mail: christian.kowalski@offis.de.

2. Method

In order to provide comprehensive support for the movement of patients, an actuated bed is to be used. For the actual support at the bed, we chose the LBR iiwa 7 R800 model from Kuka, which makes safe human-robot collaboration possible due to its sensitive joint torque sensors [3]. To bring the components together, an intermediate construction was manufactured for the actuated bed on which the robot can be mounted. For interaction with the caregiver or the patient, additional sensors are required to detect the robot's environment. For this particular case, a visual system based on multiple 3D cameras is used to detect any unwanted collision at an early stage.

3. Results & Discussion

The result of the conceptional design can be seen in Figure 1. We decided to test the system's limits by using it in a scenario where the patient (rescue dummy, 80 kg) is turned to the side, then the caregiver places the hand on the patient's thigh for the transfer towards the head end of the bed. A marker on the nurse's hand is detected by the vision system and functions as the reference for the robot goal. At this predetermined position, the robot applies additional pressure with a predefined force so that the nurse supported and hence physically relieved during the process.

Figure 1. Final setup consisting of an actuated bed, mounted robotic manipulators and a Microsoft Kinect V2 vision system. The right side depicts a potential supporting scenario using the robot.

4. Conclusion

It was possible for us to realize a robotic assistance system mounted at an actuated bed with a visual detection system, which is able to support physically during predefined nursing activities. Next, we plan to record all regular physically demanding nursing activities executed by two cooperating nurses in order to make meaningful derivations for the operation of the robot on the basis of this visual data.

Abstract. The goal of this research was to design a solution to detect non-reported incidents, especially severe incidents. To achieve this goal, we proposed a method to process electronic medical records and automatically extract clinical notes describing severe incidents. To evaluate the proposed method, we implemented a system and used the system. The system successfully detected a non-reported incident to the safety management department.

Keywords. Safety management, supervised machine learning, medical records

1. Introduction

In order to prevent medical accidents at hospitals, it is important to grasp those events at early stages that lead to severe medical accidents and then take appropriate actions based on the events. These events, which are defined as incidents, are usually reported by medical staff to the safety management department, that is responsible for the prevention of medical accidents in hospitals. The reports are analyzed by the department in order to decide which measures should be implemented by the clinical staffs. This mechanism is called an incident reporting system [1].

One of the main issues related to incidents is a long delay or even lack of reporting [2,3]. It is especially important to detect those cases since they affect the safety management departments ability to respond properly.

The goal of this research is to design a solution to detect these non-reported incidents, especially severe incidents. To achieve this goal, we develop methods to process electronic medical records and automatically extract clinical notes describing severe incidents. The extracted notes are treated as incident candidates which are shown to the safety management department for further analysis.

¹Corresponding Author: Kazuya Okamoto, Kyoto University Hospital, 54 Kawahara-cho, Shogoin, Sakyo-ku, Kyoto, 606-8507, JAPAN; E-mail: kazuya@kuhp.kyoto-u.ac.jp.

2. Methods

We develop methods to process electronic medical records and automatically extract clinical notes describing incidents of injection by using the SVM based technique [4].

First, we manually label a training set of clinical notes into two categories based on whether they include a severe incident report or not. Next, by morphological analysis, the training set is separated into words and arranged in a vector space using single words as the axes. Then, the SVM creates the machine learning models from the arranged training set with labels.

Finally, based on the created machine learning models, the SVM extracts positive clinical notes which are estimated as clinical notes with incident reports. The extracted notes are treated as incident candidates which are shown to the safety management department for further analysis.

3. Experiments

Using the proposed method based on the linear kernel SVM, we implemented an incident candidate reporting system. To evaluate the system, we asked a staffs of the safety management department to judge whether extracted incident candidates were incidents or not.

4. Results

The system extracted 121 incident candidates from the 294,731 clinical notes. 34 of them were judged to include severe incident reports by the staff of the medical safety department, which means that the precision is 28.1%. 31 of them were related to sudden critical changes of patients' conditions; other two were related to incidents during surgeries; the other was related to a fall from a bed. Moreover, several sudden critical changes among the detected incidents were not reported actually.

5. Conclusions

In this research, we aimed to establish a method to extract incident candidates from clinical notes in order to detect non-reported severe incidents. In addition, we implemented a reporting system that presents incident candidates extracted by using the proposed method. The system successfully detected a non-reported incident to the safety management department, thus our goal was achieved.

Developing a Mobile App for Patients to Monitor Medical Record Changes Using Blockchain

SungJun PARK^a, MinDong SUNG^a, Sungjae JUNG^b, Eunsol LEE^b,
Jaehoon LEE^{c,d}, Yu Rang PARK^a

Abstract. According to recent revisions to medical laws in Korea, changes to electronic medical records are to be documented. To do so, however, a transparent system with which to store original documents and changes thereto is needed. The transparency and immutability of blockchain records are the key characters of blockchain technology. Employing these characteristics, we developed an application with which to monitor changes of medical records using blockchain.

1. Introduction

Although medical records are personal to the individual patient, patients themselves often face difficulties with gaining access to their medical records, compared to medical staff. If a patient would like to determine whether their medical records have been changed, they must request all medical records at a hospital. Also, according to Korean medical law, accessing electronic medical records is to be documented.[1] An objective and transparent system with which to preserve the history of revisions to original medical data is needed. Accordingly, we developed a system that allows patients to monitor changes to their medical records using blockchain technology, which is known for its transparency and immutability.[2]

2. Method

To begin, we categorized information contained within medical documents into three risk levels: medically important and incapable of being modified; medically relevant, but capable of being modified; and medically unrelated. Unlike existing blockchain transactions, transactions used in private blockchains do not include the recipient's address, allowing for a separate variable in the blockchain to distinguish patients. The transaction structure of a blockchain block comprises four items: the Owner, Topic, Key, and Value. The Key and Value items hold four additional items: Hash, DocumentUri, PreviousHash, and Modified. The Hash item represents the unique ID of a medical record, and DocumentUri indicates the address where the medical record is stored. PreviousHash reflects the previous version of the current record of the Hash. When a medical record is entered for the first time, the PreviousHash value is entered as Null. Finally, the Modified item indicates how many changes have been made to the

medical record. This application was developed with Android Studio using Java version 1.8 and utilizes the published blockchain API.

3. Results

This application monitors the creation of medical records, changes thereto, the risk of changes, and the creation and modification timestamps through the blockchain. The processes of the application through the blockchain are shown in Figure 1.

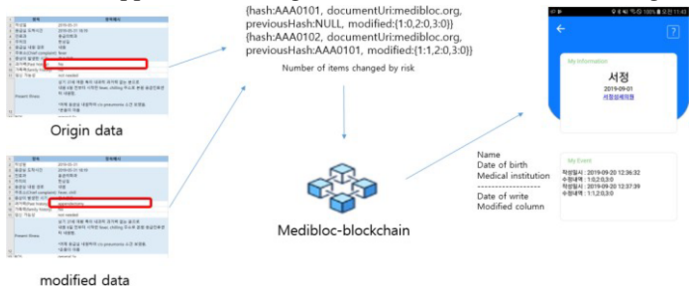

Figure1. How the application works

On the left side, the origin data and modified data are recorded in the blockchain in the same text format as the center. So you can see how many your medical records been changed or not in the application through the medibloc panacea-core API.

4. Conclusion

In this study, we established a monitoring system that allows patients to be aware of changes to their medical records using blockchain technology. Using the application, patients can be informed about the status of their medical record as soon as the record is created or changed. Adopting this system will allow for more transparent management of medical records and potentially more trust among patients in their doctors. There have been cases of building electronic medical records⁴ or personal health records⁵ with blockchain. However, only the construction of a blockchain system that stores information has been discussed, and most proposed systems have been established for only the storage and sharing of medical records. This study is the first to develop an application for monitoring changes to electronic medical records, and a prospective study on its usability is being planned. The blockchain itself is decentralized, but it's not a perfect DApp. Due to it gets its value from the database to access the app. In addition, there are still Smart contracts security issues. Therefore, DApp is discussion and limitation.

Developing and Piloting TB Medication and Refilling Reminder System in Ethiopia

Kassahun DESSIE GASHU ^{a,1}, Fedlu NURHUSSIEN ^b, Adane MAMUYE ^b, Kassahun ALEMU GELAYE ^c and Binyam TILAHUN ^a

^a *Department of Health Informatics, Institute of Public Health, College of Medicine and Health Sciences, University of Gondar, Gondar, Ethiopia*

^b *College of Informatics, University of Gondar, Gondar, Ethiopia*

^c *Department of Epidemiology and Biostatistics, Institute of Public Health, College of Medicine and Health Sciences, University of Gondar, Gondar, Ethiopia*

Abstract. This project followed waterfall model to develop a context tailored and user-friendly reminder system to support home based TB treatment. piloting was conducted on expert and patient levels. We developed a flexible and user-friendly web-based system that allows medication and refilling reminder. Participants agreed on its usefulness despite infrastructure and personal related challenges.

Keywords. Phone reminder, medication, refilling, Ethiopia

1. Introduction

Non-adherence to TB treatment worsen during continuation phase [1]. Mobile phone messaging showed promising output in supporting home-based medication [2]. Most of mHealth Apps run with smart technology but smartphone ownership is low in Africa and usability remained challenging due to poor tailoring and engagement of end-users during development process [3]. This project aimed to develop and test a web-based reminder system for home-based TB medication using both basic and smart phones.

2. Methods

The project is part of an ongoing randomised controlled trial study in Northwest Ethiopia, registered in PACTR201901552202539. The project applied a waterfall model development process and piloted at expert and patient levels. We used NetBeans, Glass Fish, Java Persistence API, java platform Enterprise Edition, JavaScript and MySQL for frontend and backend development, and Serreta modem to handle SIM cards. Piloting, involved 2 IT experts, 3 health information technicians and 4 TB focal persons to evaluate interface and layouts. To assess usefulness and challenges, 23 adult patients on continuation phase enrolled and received medication and refilling reminder for 2 months.

¹ Corresponding Author,; E-mail: kassahundessie@gmail.com

3. Result

We developed a flexible and user-friendly web-based reminder system. The main features include: registration, reminder scheduling for medication and refilling (Fig.1). About, 20(87%) of patients received all reminders. Of them, all replied the system was useful. A respondent replied: *“Rural people like me are busy and forget pills. This system helped me lot.”* (42Y/O, M). Participants reported: weak mobile network, power inconsistency, medication time variation (4(17%) patients follow suggested time).

Figure 1. Patient registration and cell phones based text (Amharic) and graphic reminder for TB treatment

4. Discussion

The current project developed a context tailored, user-friendly and flexible web-based reminder system for home-based TB treatments. Globally, various generic mHealth systems developed, however, usability and sustainability often determined based on contexts [4]. In resource limited setting where no reliable ICT infrastructure, low digital literacy and low access to smartphone and needs to consider those factors during development [5]. The mobile cellular subscriptions shown fastest growth 74% in Sub-Saharan Africa including 51% in Ethiopia [6]. Therefore, development of mHealth technologies need to assess local requirements and tailored to the context. As a limitation, this reminder system works only with text and simple graphic messages.

5. Conclusion

A context tailored reminder system could be usable for home-based TB treatment in low resource settings. The randomised controlled study could address its efficacy.

Development of a Graph-Based Database for Ovarian Cancer Symptoms

Young Ji LEE^{a,b1}, Harleigh NIYU^c

^a*School of Nursing, University of Pittsburgh, USA*

^b*Department of Biomedical Informatics, University of Pittsburgh, USA*

^c*Department of Mathematics and Computer Science, Duquesne University, USA*

Abstract. Uncontrolled cancer-related symptoms severely affect the quality of life of cancer patients. This study leveraged symptom data written in the online health communities (OHCs) and developed a symptom knowledge database for cancer patients. Further study is needed to apply this pilot study to the larger OHCs data.

Keywords. graph-based database, text mining, consumer health informatics

1. Introduction

Uncontrolled cancer- and treatment-related symptoms not only severely affect the quality of life, but also decrease the overall survival rate of cancer patients [1]. In the Internet era, many patients share their symptom experiences on online health communities (OHC) that is not attainable from clinical data [2]. However, it is difficult to utilize the information written in the OHCs without a standardized approach to discover and manage information. Thus, there is a need to develop a pipeline to utilize this wealth of information for cancer research and clinical practice in the future.

The overarching goal of the study is to develop a symptom knowledge database for cancer patients. As a pilot study, we will focus on ovarian cancer (OvCa). OvCa is a strong example for understanding the complex challenges of managing symptoms because OvCa patients have a wide range of tumor types and many face a lifetime of ongoing active disease management due to high recurrence rates [3].

2. Methods

Data was collected from the OHC sponsored by the American Cancer Society: Cancer Survivors Network (<http://csn.cancer.org/forum/132>). We extracted posts that were posted between January, 2006 and March, 2016 (n=50,626). As a pilot study, we randomly selected 100 postings that described “nausea” and manually annotated them in four concepts: symptoms, treatments, results and other medications. After annotation, each concept was entered as a node in the Neo4j (<https://neo4j.com/>), an open-source graph-based database, allowing us to visualize data in an easily understood manner.

¹ Corresponding Author, School of Nursing, University of Pittsburgh, 3500 Victoria Street, Pittsburgh, USA 15213; E-mail: leeyoung@pitt.edu.

3. Results

Our current database includes data from 88 users either an OvCa patient or caregiver of OvCa patient and 266 nodes. We have identified 27 symptoms including “nausea”, 10 cancer-related treatment (e.g. Taxol, cisplatin) and 4 different effect of treatments. We also identified 6 co-existing medical conditions and 31 non-cancer related medications such as Tylenol. Current database includes 5 types of relationship between nodes: “diagnosed_with”, “has”, “resulted_in”, “takes”, and “underwent”. Figure 1 showed an example of graph-based database.

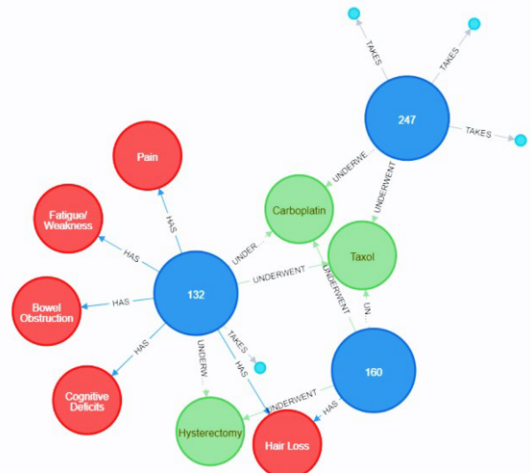

Figure 1. Example of nodes and relationships described in Neo4j

4. Discussion and Conclusion

We found that OHCs can capture more symptom related information compared to the current symptom assessment checklists. Furthermore, it is crucial to understand relationship between symptoms in a symptom cluster since cancer symptoms exist as a cluster of symptoms rather than a single symptom. Further study will apply natural language processing to automate the annotation process for larger datasets and capture additional factors (e.g., age, cancer stage, race, and author type) from the OHCs.

Our pilot study showed the potential of OHCs in the nursing research and clinical practice to understand cancer symptoms from the patients’ perspectives that have not been captured in the clinical setting. We believe that this will guide clinicians and researchers about to consider when designing interventions for managing symptoms.

Development of a Personalized mHealth Program for Cancer Symptom and Complication Management

Lixin SONG,^{a1} Eno IDIAGBONYA,^a Kevin SU,^a and Juliet IDIAGBONYA^a

^aSchool of Nursing & LCCC University of North Carolina-Chapel Hill

Abstract. Based on care need assessment of colorectal and bladder cancer (CBC) patients with newly created ostomies (stomas) and caregivers, and with the input of the Wound, Ostomy, and Continence Nurses (WOCNs), we have developed an mHealth complication and symptom monitoring and self-management program, titled *PRISMS*.

Keywords. cancer, patient-reported outcome, symptom management

1. Introduction

Ostomy creation is one of the major treatment options for colorectal and bladder cancer (CBC), the third and fifth most common cancers in the U.S., respectively.¹ Up to 80-90% of CBC patients with new ostomies experience dehydration, infection, and other symptoms and complications after being discharged from hospitals.^{2,3} The symptoms and complications are associated with reduced quality of life (QOL),⁴ depression and anxiety, and increased ER visits, hospital readmission,^{3,5} and high costs of care.³ This study aimed to develop an mHealth intervention to enhance personalized supportive care and improve QOL for cancer patients and caregivers during care transition from ostomy creation professional care in the hospital to self-management at home.

2. Methods

We conducted mixed-method formative research to identify the care needs among post-discharge CBC patients and their caregivers. Based on analysis of the data abstracted from Reddit (www.reddit.com/) (n=206 patients and caregivers) and from a large survey among caregivers through the Bladder Cancer Advocacy Network (BCAN) (N=559), and qualitative interview of WOCNs, we have developed a web-based mHealth complication and symptom monitoring and self-management program, titled PRISMS.

3. Results

3.1. Social media analysis. We found most of the posts were written by children of patients (n=62, 55%), followed by patients themselves (n=33, 29%). Patients looked for support from others who have had similar experiences (peer support) (n=33, 29%) and talked about their physical symptoms and psychological/emotional struggles (both n=29, 26%). Family members expressed psychological/emotional struggles (n=42, 37%), asked

¹ **Corresponding author:** Lixin Song, PhD, RN, FAAN, University of North Carolina-Chapel Hill, Carrington Hall, Chapel Hill, NC 27599-7460. Tel: 919-966-3612. Fax: 919-843-9900. Email: lsong@unc.edu

for advice on how to provide emotional and behavioral support to the patient (n=24, 21%), and sought peer support (n=15, 13%). Other post-treatment supportive care information needs included future quality of life (n=19, 17%), treatment side effects (n=11, 10%), and medical/financial resources (n=10, 9%).

3.2. BCAN survey. The majority of caregivers in this cross-sectional online survey were spouses or partners, female, and college-educated or higher. Mean age of caregiver was 61 years (21-85). Although caregivers needed support for physical well-being, more than two thirds needed emotional support. Web-based programs and peer support were most preferred intervention format

3.3 PRISMS development. Based on these results, a literature review, and the input of WOCNs (N=3), we identified the following needs of CBC patients with ostomies and caregiver: continuous access to post-discharge supportive care at home, knowledge of symptom and complication monitoring and management, and support from peers and professionals. We developed PRISMS to address these needs, to reduce symptoms and complications, and ultimately, to improve the QOL for both patients and caregivers and reduce unnecessary ER use and readmission for patients. PRISMS' features include:

- a) Supportive care needs for the most common post-surgical symptoms and complications, e.g., fatigue, dehydration, skin care, sleep issues, and emotional distress;
- b) Scalable self-management program used in home settings that can provide self-monitoring and self-care guidance, communication with peer patients and caregivers, and access to health care professionals if needed.
- c) Knowledge and skills training for symptom and complication management, moderated online forum for peer and professional support, and other resources.
- d) Integration of PRO and objective data from wearable devices to provide continuous monitoring of patients' symptoms and complications.
- e) Use of plain language to accommodate health literacy needs for this population that is mostly comprised of seniors: <https://www.plainlanguage.gov/>

3.4 *We have completed user testing of the PRISMS prototype among 10 nurses and physicians, as well as 10 CBC cancer patients with ostomies and their caregivers who have been extremely enthusiastic about the features of PRISMS and also provided useful information for refining PRISMS.*

3.5 *We will conduct a 3-arm pilot randomized trial for feasibility testing among 45 CBC cancer patients and their caregivers in the next 12 months.*

Development of a Questionnaire to Measure Healthcare Providers' Satisfaction with Telemedicine Services

Esmée TENSEN^{ab,1}, Youri BROEKHUIZEN^{ab*}, Johan van BUGGENUM^{a*}, Leonard WITKAMP^b, Monique JASPERS^a, and Linda PEUTE^a

^a*Amsterdam UMC, University of Amsterdam, Department of Medical Informatics, Amsterdam Public Health Research Institute, Amsterdam, Netherlands*

^b*Ksyos Health Management Research, Amstelveen, Netherlands*

**Second and third author contributed equally*

1. Introduction

With the advent of technology in healthcare, healthcare providers (HCPs) are increasingly using telemedicine services that enable them to diagnose or treat patients by means of digital remote consultation of a specialist. Due to their shown cost-effectiveness and proven quality of care, telemedicine services have now permeated a wide variety of fields such as cardiology, ophthalmology, and dermatology. HCPs' satisfaction (i.e. needs, wishes and expectations) with these services in health practice is a primary factor in the usage, acceptance and sustainability while dissatisfaction with these services will reduce their willingness to use the system. However, a validated questionnaire focusing on HCPs' satisfaction with the use of integrated telemedicine services is lacking. We aim to develop such a tool. This validated instrument will capture individual perspectives on telemedicine services independently and confidentially. This abstract describes the steps followed to develop a first version of the questionnaire.

2. Method

Dutch experts from a telemedicine healthcare organization (Ksyos) participated in this project. Ksyos works with 12,000 HCPs; medical specialists, paramedics and GPs. First, an explorative literature search was conducted to acquire existing validated questionnaires on job-, communication-, and telehealth service satisfaction in healthcare. Two validated questionnaires, the staff satisfaction questionnaire used in the Basque health service and the telehealth usability questionnaire (TUQ), were explored to develop a list of potentially relevant constructs as input for our questionnaire [1,2]. Second, an appreciative inquiry of all revealed constructs was performed with a Ksyos domain expert and a human factor expert. Third, the questions were forward translated to Dutch by two researchers. Then, a focus group with account managers and a customer service employee was held to discuss the resulting constructs that would form the basis for the first version of the questionnaire. We used their input because they

¹ Corresponding author: Esmée Tensen, E-mail: e.tensen@amsterdamumc.nl.

have frequent contact with HCPs who use telemedicine services. During the focus group meeting consensus was reached by rating all constructs on relevance. Question formulation and applicability to the construct were likewise discussed. Questions could be added if construct seemed missing or changed if in need of rephrasing. Fourth, a pre-testing of the questionnaire took place among HCPs in two rounds. Eighteen HCPs received a PDF-document with all the questions (e.g., "I believe [*name telemedicine system*] suffices in fulfilling my wishes and expectations for telemedicine") and were also asked to review each question phrasing in the document and, for certain questions, the applicability to their context. In the end, the questionnaire was built in an online questionnaire tool (LimeSurvey) and an invitation link was sent to another 21 HCPs to check for technical problems with filling in the digital questionnaire and to measure the needed completion time.

3. Results

The two questionnaires from the literature resulted in a list of 20 potentially relevant constructs. After the appreciative inquiry, three construct themes were not applicable within the current research setting and deleted. The focus group led to textual and contextual changes to the phrasing of the questions. Nineteen of 58 questions were rated as 'not relevant', four questions were added and two questions were merged. Respectively 10/18 and 8/21 unique HCPs participated in two pre-testing rounds. Again, textual changes were made based on terminology, three questions were removed and four questions were added in this phase. Besides the background characteristics, the remaining 49 questions could be classified in seven themes: working conditions, training, pay, communication, organization and policy and strategy, interaction with the telemedicine system, usage of the telemedicine system. Average questionnaire completion time was 9 minutes (2nd round) and no technical problems occurred.

4. Discussion and conclusion

Positive contributions of telemedicine on quality and costs of care are essential and shown. Equally important is to understand if, why and what makes HCPs embrace these innovative care services. HCPs' satisfaction with telemedicine from different perspectives is ideally measured by use of a questionnaire. Such a tool may also allow telemedicine service benchmarking on quality criteria from the HCP perspective in different care fields. Based on a structured pre-testing approach, we developed a first version of a telemedicine service questionnaire. One of our limitations is that our current version of the questionnaire was mainly based on the store-and-forward context of the Ksyos system and therefore did not focus on direct video consulting services.

Development of a Smart e-Coach Recommendation System for Obesity

Ayan CHATTERJEE ^{a,1}, Martin W. GERDES^a and Santiago MARTINEZ^b

^aUniversity of Agder, Faculty of Engineering and Science, Grimstad, Norway

^bUniversity of Agder, Faculty of Health and Sports Sciences, Grimstad, Norway

1. Introduction

By 2030, 8 out of the 10 leading causes of death will be linked to risk conditions of ‘Lifestyle diseases’, irrespective of gender [WHO]. Obesity is one of the major lifestyle diseases that lead to other health conditions, such as cardiovascular disease, chronic obstructive pulmonary disease, cancer, diabetes type II, hypertension, and depression. e-Health monitoring has become increasingly popular providing ICT-based remote and timely care support to patients and healthcare providers. In our research, we are working on a smart e-Coach solution to perform regular monitoring of health and wellness parameters related to obesity. We are going to develop a smart e-Coach system utilizing ICT, IoT and AI technologies to provide individual behavioral recommendations aiming at a healthier lifestyle to prevent obesity.

2. Method

We have divided our project work into the following task groups based on the well-established design-science-research methodology: (1.) Systematic literature review; (2.) Design and development (feasibility study, data collection, development of a recommendation engine, e-Coaching through interaction); (3.) Trial run; and (4.) Model evaluation with performance parameters (goal achievement). The feasibility study includes (a.) What to measure? [independent variables (e.g., demographics) and dependent variables (e.g., weight)]; (b.) How to measure? [spending time to explore and find the right instruments and methods]; (c.) Type of data to be collected [personal, physiological, contextual and behavioral] and determination of data collection process; (d.) Policy for the recruitment of the participants; (e.) Preparation of consent form; (f.) Ensuring data security and privacy; (g.) Use of a standard framework for eHealth intervention and determination of its efficacy. This research is deeply focusing on **“What to coach” and “How to coach”, including** the design, development, testing and evaluation of observational evidence-based, context specific and individual obesity recommendations. We have targeted group size of participants to 50-99 in Norway within an age group of 18-40 (both male and female). Healthy participants will be recruited on voluntary basis following a physical condition check and a consent form

¹ Corresponding author E-mail: ayan.chatterjee@uia.no.

[approved by the Regional Komiteer for Medisinsk og Helsefaglig Forskningsetikk (REK, <https://helseforskning.etikkom.no/>)] handover process during recruitment.

3. Results

The project is in an early design phase with the focus on the data collection part. We have designed a solution architecture to collect data from participants and store them securely. We are working on the 'eHealth ontology design' that is another important part in our study to support the structuring and to establish interoperability between different heterogeneous system components and networks. In this poster presentation, we will demonstrate charts and diagrams related to 'Health and Wellness Data Collection Process', 'Type of Data to be Collected', 'Solution Approach', and 'eCoach Recommendation plan for Achieving Goal'.

4. Discussion

The analysis of the problem space has shown three research directions that we will follow in this research: (1.) Data acquisition and its security; (2.) Health risk prediction; (3.) Personalized e-Coaching. We have targeted three main problems to solve in this research project: (a.) Creation of a compact, intelligible abstraction from massive, unintuitive raw, unstructured observations for health and wellness data (e.g. sensors, user preferences, questionnaires.) using an eHealth ontology; (b.) Protection against illegitimate access to the system and EHR; (c.) Development of a digital e-Coach system to model meaningful, observational and empirical evidence-based, context specific, automatic, personalized recommendations to achieve health wellness goals, and to advise about physical activity, nutrition, medication, and other relevant factors for healthier lifestyle. The digital e-Coach system will capture physiological (blood pressure, heart rate, blood cholesterol, blood glucose, height, weight), contextual (time, location, environment, social), and behavioral (activity, nutrition, sleep) data over time from secure wearable sensors, customized questionnaires, interviewing, apps, feedback forms and minimal-invasive way. Time series analysis of collected data will help to determine day-by-day random variation in lifestyle, weekly variation, seasonal variation, variation in diet, meal pattern, true changes in diet over time, and behavior change. In the recommendation process, participants will be given personalized, evidence-based, contextual recommendations and motivation (related to activity, nutrition) for long-term goal evaluation to keep BMI in the range of 18.5 - <25.

5. Conclusion

We are working on the assumed hypothesis that an effective e-Coach mechanism can reduce the obesity risk with automatic generation of personalized recommendations. Integrating offline (human) coaching psychology to an e-Coach, selection of an effective recommendation plan and improving it further to reach the convergence criteria (overweight to normal weight) is a computationally hard problem that we have planned to solve in our research with eCoach behavioral (diet, activity) interventions.

Development of a Systematic Text Annotation Standard to Extract Social Support Information from Electronic Medical Records

Camila VOLIJ^{a,1} and Santiago ESTEBAN^a

^a*Family and Community Medicine Division, Hospital Italiano, Buenos Aires, Argentina*

Abstract. The influence of social relationships on mortality is comparable with that of standard clinical factors. In order to extract this information via supervised NLP algorithms, clinical notes have to be annotated manually. At present we did not find any systematic annotation standards to extract social support. In this work, we developed a systematic text annotation standard to detect social support in couples from electronic medical records.

Keywords. Social Support, Electronic Medical Record

1. Introduction

The influence of social relationships on mortality is comparable with that of standard clinical factors such as smoking, obesity and hypertension [1]. In the last few years, the National Academy of Medicine recommended that social support be documented in electronic medical records (EMRs) [2]. Social determinants of health, and particularly, social support is usually recorded in free text form within EMRs. In order to apply supervised natural language processing pipelines (NLP) to extract this information, texts have to be manually annotated. Nevertheless, we were unable to find any systematic annotation standards for social support comparable to other already existing standards (i.e. TimeML). Thus, in this work we aim to develop and test an annotation standard that allows to create supervised datasets in order to extract information on social support from life partners.

2. Methodology

First, based on Valtorta et al. [3] systematic review, we thoroughly reviewed 54 questionnaires on social support. Subsequently, a research committee of EMR specialists and users from our institution, evaluated the various questions and selected those that were considered, a priori, that could be answered via the EMR. Finally, we developed an

¹ Corresponding author;; E-mail: camila.volij@hospitalitaliano.org.ar.

annotation standard that allowed us to describe the social support provided by a life partner defining entities and exploring the relationships between them.

3. Results

After the literature search and the focus groups with professionals, we defined social support from life partners in two dimensions: structural and functional support. We operationalized structural support by means of five variables: 1) Is there a mention of a type of personal relationship status? (true/false); 2) Does the relationship status refer to the patient (true/false); 3) What type of relationship status is mentioned (married, widower, 'in a relationship', single, etc); 4) Is the patient currently in a stable relationship? (true/false); 5) Is the patient currently living with whomever she is in a relationship with? (true/false).

We operationalized functional support using four variables: 1) Is there a mention of active social support in the text (true/false); 2) Is the patient the recipient or the provider of social support?, 3) Is the mention of social support positive or negative?, 4) Type of social support (psychosocial, healthcare related, general care related).

We tested our annotation standard on a random sample of 2000 clinical notes that were previously filtered using a keyword-based filter (the filter had a positive predictive value of 81% and negative predictive value of 99% for detecting texts with mentions regarding social support from a life partner in an unfiltered random sample of clinical notes). 96% of those 2000 clinical notes had mentions on the patient's current relationship status. Of these, 75% described stable relationships and 8% of them, that the patient and their partner lived together. Regarding functional social support, 28% of the notes mentioned some type of social support. Of those notes 90% mentioned the patient being the recipient. Lastly, in 89% of these notes the support was positive.

4. Discussion and Conclusion

The systematics of text annotation presented in this work, although presented as an innovative and efficient way of detecting intra-social support, has as a limitation the construct itself being difficult to define and therefore to measure even with questionnaires well known. Defined variables and their categories may be used for the creation of systematic annotation of texts on family social support, intra-friends, within institutions, among others.

Digital Health Interventions for Diabetes Self- Management Education/Support in Type 1 & 2 Diabetes Mellitus

Dumisani NKHOM^a Charles Jenya SOKO^a Pierre BOWRIN^{tb} and Usman IQBAL^{a,b,c},

^a *Masters' Program in Global Health & Development, College of Public Health, Taipei Medical University*

^b *PhD Programs in Global Health & Health Security Dept., College of Public Health, Taipei Medical University*

^c *International Center for Health Information Technology (ICHIT), Taipei Medical University*

Abstract. Introduction. Diabetes Mellitus is a major global concern. DSME (Diabetes Self-Management Education and Support) helps improve outcomes. Over the years, newer technologies have delivered DSME warranting an update of evidence. **Objectives:** Describe current digital health interventions employed in DSMES and their effectiveness in improving glycemic control and quality of life of Diabetes Mellitus (DM) patients compared to usual care. **Methods:** Systematic review design and meta-analysis. We will search data from 2010 to 2019. The review will only include randomized control trials (RCTs) with digital health interventions (mobile health, social media, e-health) as the main intervention to deliver DSMES. **Expected Results:** We expect digital health intervention-led DSMES to improve target outcomes compared to usual care. This study will aggregate information on usage and challenges for these tools. It will also suggest the direction of effect of such tools in different populations.

Keywords. Diabetes Self-Management Education and Support,

1. Introduction

Diabetes Mellitus is a major global concern and a costly disease. Currently, Diabetes Mellitus is a top ten global killer of humans. One method to improve outcomes and reduce costs is Diabetes Self-Management Education and Support (DSMES). DSMES also helps in preventing occurrence of complications. Ideally, quality DSMES should be easily accessible, however, its availability varies with different health systems. Digital health interventions help to solve these challenges with varying success. In addition, continuous digital innovations warrant up-to-date evidence for digital health interventions in DSMES. Therefore, we aim to know: What digital health interventions are being used in DSMES to improve glycemic control, Diabetes knowledge and health-related quality of life (HrQoL) for people with T1DM and T2DM in the past 10 years? & What is the effectiveness of digital health interventions for DSMES in improving glycemic control, Diabetes knowledge and HrQoL as compared to usual care for people with T1DM and T2DM in the past 10 years?

2. Methods

Design will be systematic review and meta-analysis. The study framework and reporting will be done in accordance to Preferred Reporting Instrument for Systematic Review and Meta-Analysis (PRISMA). We will search literature from the following databases: PubMed, EMBASE, Cochrane Library, Web of Science and Scopus. The review will only include randomized control trials (RCTs) published between 2010 and 2019 comparing digital health interventions delivering DSMES to usual care focusing on glycemic control, HrQoL and Diabetes Knowledge. Studies targeting other populations apart from confirmed Type 1 and 2 DM patients will not be included. In this review, healthcare that does not include use of digital health interventions will be considered as usual care. Protocol is registered on PROSPERO CRD42019139884. Articles are going to collected into Endnote X9. Studies will be screened against the eligibility criteria when looking at the titles and abstracts. Full text review will be done by two reviewers with disputes resolved through consensus.

Table 1: Proposed study variables that may help explain effect of digital health interventions on outcomes

Population	Interventions	Study	Outcomes
Age, sex, sex ratio, ethnicity, sample size, country, education level, disease type, duration of disease	Digital category Description Length Frequency Follow-up time	Setting Design Theoretical framework Comparison Author Journal Year of publication	HbA1c HrQoL Knowledge Instruments used Scales used

We will adapt Cochrane Collaboration’s data extraction form. Missing information will be sought through emails. Differences will be resolved through consensus or consulting a third reviewer

1.1 Analysis

Variables will be summarized using descriptive statistics. We will use Cochrane Risk of Bias (ROB)-2 tool for parallel and cluster randomized studies. Assessment will be done independently by two reviewers, reaching consensus on differences. Random effects meta-analysis will be performed according to Diabetes type, digital health intervention route at various time points using Comprehensive Meta-Analysis Software Version 3 (Biostat, USA). Outcomes will be collected in one measuring unit or be aggregated using standardized mean difference. Qualitative analysis will assess acceptability & feasibility of digital interventions. Findings from subgroup analysis and meta-regression will help explain interaction of study variables with outcome estimates. The above will considered of great clinical importance. Publication bias will assess across studies.

2. Expected Results

We expect digital health intervention-led DSMES to improve target outcomes as compared to usual care. This study is expected to aggregate information on common usage and challenges for these tools. It will also inform us the direction of effect of such tools in different populations and environments. This study will be an addition to literature in support of Sustainable Development Goal 3 in the fight against non-communicable diseases and in ensuring universal health coverage.

Electronic Medical Records Virtual Course. Strategies for an Effective Training

Daniel A. RIZZATO LEDE^a Cintia D SPERANZA^a Florencia ALEGRE^a

Adriana CANTORA^a Emilio PANIZZA^a Ariadna POU^a

^a *Ministry of Health, Argentina*

Abstract. The Introductory Course to the Electronic Medical Records (EMR) is part of the Digital Health Strategy of the Ministry of Health's Universal Health Coverage (UHC). One of its principles is achieving interoperability between different electronic medical records systems. The healthcare workforce training in these subjects is essential. During 2018, six editions of the course were developed in the Moodle Virtual Health Platform with 850 approved participants. We analysed the previous experience to reformulate the learning materials and create new instances for pedagogical support.

Keywords. eLearning, Electronic Health Records, Change Management.

1. Introduction

According to the Ministry of Health (MoH) Resolution 189/2018, Digital Health is one of the three strategic principles to achieve Universal Health Coverage in Argentina. Interoperable EMR can store primary information during contact with the patient to build a national medical record with clinical, statistical and management utility.

Evidence shows that the implementation of any EMR is a complex process that may have to overcome multiple barriers: financial, technical, time, psychological, social and resistance to change [1]. Negative beliefs of social and psychological nature play a significant role in resistance to adopt EMR [2]. The potential of eLearning for health professionals is widely researched and reported [3]. The EMR online educational course for health professionals develops arguments to tear down usual adoption barriers, and challenges every student to become a champion of change to transform his own work practices. We analysed our previous online courses experience to reformulate the learning materials and enhance the pedagogical support.

2. Materials and Methods

Argentina has a decentralized federal organization divided into 24 jurisdictions. In its territory there are about 30,000 health centers of all levels of complexity that provide care for 45 million people. Around 60% of the population has fixed Internet access and there are 30 million users with mobile connectivity. Health workers are heterogeneous in digital literacy, but most of them interact with technological tools.

Taking into account the amount and distribution of potential students (3,000 for the first stage), the virtual self-administered course was planned to be available

periodically in the Moodle Virtual Health Platform of the MoH, at no charge. Flexibility is one of the features that makes virtual education particularly suitable for most citizens, mainly adults [4]. After 6 cohorts, 850 students passed their examinations. Quantitative and qualitative data was gathered from course enrollment, follow up, passing rates and feedback surveys. Following a technical review, the course was redesigned to ease usability and comprehension. New cohorts were also analyzed.

3. Results

The original course had 3 sections: 1) General aspects of EMR; 2) Privacy, Confidentiality and Security; 3) Interoperability. The new edition kept the same sections, with great didactic evolution in: Language (technicalities were avoided, explicit references to more complex concepts were included); Content (simplification of complex concepts focusing on the main idea); Applicability (examples were provided to enable correlation with professional practice); Audiovisual tools (short videos and animations with clear locution voice, infographics to synthesize theoretical notions); Interaction (an online forum to answer questions and promote student exchange); Exams (focus on global understanding of central ideas); Follow up (enrollment in an alumni forum to exchange local experiences).

Table 1. Number of enrolled and approved students during the last 3 cohorts of the online course (2019).

Number of students	7 th edition	8 th edition	9 th edition
Enrolled / Finished / Approved	397 / 182 / 163	561 / 242 / 220	388 / 179 / 157

Online surveys showed a trend towards better student perceptions. Table 1 shows the outcomes of the new course. Even though there was more than 50% dropout, there was a higher passing rate.

4. Conclusion

This course redesign aims to exploit the potential of e-Learning by identifying the better approach to teach about EMR in our context. The flexibility in space and time of online tools combined with proper contents favor the achievement of the strategy objectives. Enabling the MoH Moodle Virtual Health Platform for mobile devices could increase the benefits of this modality, including higher enrollment and retention.

Electronic Medication Administration System Supports Safe Medication Administration

Jenni SANTAVIRTA^{a,1}, Anne KUUSISTO^b, Kaija SARANTO^c, Tarja SUOMINEN^d
and Paula ASIKAINEN^c
^{a, b, c} *Satakunta Hospital District*
^c *University of Eastern Finland*
^d *Tampere University*

Abstract. The purpose of this study is to describe nurses' views of what supports safe medication administration in the current electronic medication administration system. Data was collected at the turn of 2014–2015 and open-ended answers were inductively analyzed using content analysis. The system's usefulness, good usability, and the feature that there is extra information available on medications and the patient-specific information needed in medication administration are elements that support safe medication administration. The study identifies wide support for the electronic medication administration system in safe medication administration.

Keywords. Safety, medication administration, electronic medication administration system, nurse

1. Introduction

Prevention of medication errors and avoidable adverse events^{1,2} is an important part of patient safety¹ and nurses' work². The use of electronic medication administration system has been found to reduce the rate of medication errors in medication administration recording and their potential future risk³.

The purpose of this study is to describe nurses' views of what supports safe medication administration in the current electronic medication administration system.

2. Methods

This study is part of wider electronic health record implementation research. Data was collected from special health care in one hospital district in Finland with one two-part open-ended section of the back-translated Medication Administration System - Nurses Assessment Scale (MAS-NAS) (N=855). In the open-ended section, nurses were asked to write down their comments about the current medication administration system and

¹ Jenni Santavirta, Corresponding author, Sairaalan tie 3, 28500 Pori, Finland; E-mail: jenni.santavirta@satasairaala.fi.

the degree to which the components of the current system enables them to administer medication safely and professionally. In this study, we report answers that described support for electronic medication administration system (eMAS) in safe medication administration. The data was collected during one month at the turn of 2014–2015. At that time, the respondents used the eMAS partly, completely, or not at all. The eMAS included an electronic home medication chart, electronic ward medication chart, and electronic prescription. Open-ended answers were analyzed inductively using content analysis.

3. Results

A total of 123 nurses answered the open-ended section; 80 of them had used eMAS partially or completely. Twenty nurses described what supports safe medication administration in the current eMAS; 15 of them reported that they had used eMAS partially or completely. Twenty-eight simplifications were formed. The eMAS elements that support safe medication are the system's usefulness to user, system's good usability, and the feature that there is extra information available in the system of medications and the patient-specific information needed in medication administration. Usefulness of the system was described as clarity of information, automated warning alerts, and continuity of medication. Good usability of the system was described as good technical quality and ease of use. Extra information available in the system was described as seeing the information needed in medication administration, such as information on medication preparation. Availability of patient-specific information needed for medication administration was described as the opportunity to read the medication list and prescriptions being in the patient record.

4. Discussion and conclusion

Nurses identified elements in the eMAS that support safe medication. Elements that support safe medication were the system's usefulness, usability, and availability of information needed for medication. Because one of the most important parts of nurses' work is to administer medication safely², nurses' opinions of how the system supports safe medication administration should be taken into account. The study identifies that eMAS widely supports safe medication administration. Further development of the systems should ensure that the system is useful for nurses, its usability is good, and the information needed for medication administration is available for nurses.

Emotion Analysis Using Electrodermal Signals and Spiking Deep Belief Network

Nagarajan GANAPATHY¹ and Ramakrishnan SWAMINATHAN

*Non-Invasive Imaging and Diagnostics laboratory, Department of Applied Mechanics
Indian Institute of Technology Madras, Chennai, India - 600036*

Abstract. In this work, an attempt has been made to discriminate arousal and valence dimensions in Electrodermal Activity (EDA) signals using Spiking Deep Belief Network (SDBN). EDA signals having different arousal and valence dimensions are obtained from public online database. These signals are divided into equal parts and normalized using channel normalization. Later, signals are subjected to SDBN for event-related features and classification. A leave-one-out cross validation is used to investigate the classification performance. The result shows that the SDBN classifiers are able to discriminate the emotional states. The network yields better classification performance for emotional dimensions of arousal and valence. It appears that the proposed approach can be used to differentiate autonomic and pathological conditions.

Keywords. Emotion, Electrodermal Activity, Spiking Deep Belief Network,

1. Introduction

Emotions are the fundamental component of human social interactions. It is necessary for behavior, perceptions and decision making. Analysis and recording of Electrodermal Activity (EDA) signals are widely used for the classification of emotions. Deep learning architectures are used for the automated recognition of emotions using physiological signals [1].

2. Methods

For this study, EDA signals are considered from publicly available DEAP database [2]. These signals are digitized at sampling rate of 128 Hz, each one minute in length and are obtained from 32 subjects. These signals are preprocessed and divided into 60 equal segments. The segments are applied to Spiking Deep Belief Network (SDBN) for training. A two-layer 50-50 neurons SDBN architecture is used for this study. Weights at individual nodes are updated using Leaky Integrate-and-Fire (LIF) neurons. The activation probabilities of LIF neurons is identified using an accurate rate-based approximation. The standard dynamics of the LIF neurons is given by [3]:

$$\tau_m \frac{dv}{dt} = E_{res} - V_{mem} + M_r \left(\sum_{i=1}^n w_i \sum_{j=1}^{m_i} \delta(f_i - f_{t_j}) \right) \quad (1)$$

¹ Email:info.nagarajan@gmail.com

where τ_m is the membrane time constant, E_{res} represents the resting potential, and M_r depicts the membrane resistance, n represent the number of incoming synapses, m_i depicts the number of spikes arriving at that synapse, $\delta(ft)$ is a Dirac-delta function set as zero except for the firing times ft_{ij} of the i^{th} input neuron.

3. Results and Discussion

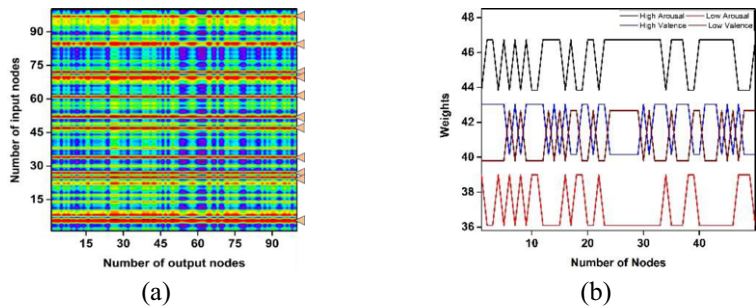

Figure 1. (a) The fine-tuned DBN weights in the second layer, and (b) A typical EDA signal class signatures generated by SDBN for classification

The visualization of fine-tuned DBN weights at the second layer is shown in Fig. 1(a). The critical features obtained in the second layer are highlighted using solid triangles. It is observed that the critical features are sparse and represents the abstract characteristics of various emotional states. The signatures of arousal and valence class generated by the SDBN for the classification are shown in Fig. 1(b). It is seen that the class signatures of arousal states are distinct from each other. In comparison to arousal class, valence class are also found to have different signatures. The classification performance of the proposed network are shown in Table 1. It is seen that the proposed approach obtained an average accuracy of 72.08% and 68.90% for arousal and valence states, respectively. It is also observed that the proposed approach obtained a precision of 74.70% for arousal class. In case of valence class, the proposed approach obtained the higher recall rate of 61.06%.

Table 1: Classification performance of SDBN architecture

Class	Accuracy	Precision	Recall
Arousal	72.08	74.70	83.23
Valence	68.90	50.96	61.26

Evaluating the Use of a CPOE for Chemotherapy Protocols

Jimenez, C^a, de Matos Lima, S^a, Luna, D^a

^a *Department of Biomedical Informatics, Hospital Italiano de Buenos Aires, Argentina.*

Abstract. Chemotherapy drugs are one of the most common causes of serious and fatal medication errors, especially during prescribing, where computerized physician order entry (CPOE) take on importance. This study proposes the description of the post-implementation status of a CPOE in a highly specialized hospital between January and June 2018, among patients older than 18 years. Results: a total of 8835 protocols were indicated using the specific CPOE (93% use rate over all protocols) 91% completed the administration, 1.2% were rejected by pharmacy, and 6.8% was canceled. The most frequent cause of rejection by pharmacy and cancellation by oncologist was an inadequate dose. Most of the protocols indicated using the CPOE implemented, with a reject by pharmacy rate of 1.2%, indicates the utility of CPOE as an error prevention strategy.

Keywords. Computerized provider order entry, oncology, chemotherapy

1. Introduction

Chemotherapy drugs are characterized by low therapeutic index and significant toxicities at clinically prescribed doses, which, added to the vulnerability of patients with cancer, raises serious problems of drug safety [1]. Medication errors can occur at any stage of the chemotherapy process, especially at the prescription stage [2]. The most common source of error was within the order phase and that, compared with non-chemotherapy medication errors, could rise up to 48% more likely to be serious in nature [3]. The safety of chemotherapy has been a long-standing issue, particularly because is a complex process, with multiple steps and health professionals involved in the prescription, dispensing and administration of these agents [4][5]. CPOE is associated with a significant reduction in preventable adverse drug events [6] and focusing on chemotherapy, most studies find beneficial when compared to paper prescription [7].

2. Methods

A descriptive cross-sectional study was carried out in order to study the amount of oncological prescriptions made from the specific CPOE.

3. Results

During the study period, a total of 10475 protocols were indicated, of which 1380 were excluded from the San Justo center (other medical center in the network), 255 since they did not have an assigned sector and 5 protocols that were indicated in a pediatric area, giving a total of 8835 protocols. Each of the protocols corresponds to a patient. The CPOE was used in 93% of the oncological prescriptions. The remaining 7%

corresponded to indications on paper, drugs not approved by the Committee of the Cycle of Medication and drugs of research protocols. There was a total of 195 protocols loaded in the management system, of which 146 were indicated. There was an average of 1472 protocols per month. A total of 7602 (91%) protocols were finalized. Oncology pharmacy put in review 107 protocols (1.2%). The number of canceled protocols 602 (6.8%) includes both those canceled by medical initiative and those placed on review by pharmacy. In 41% (249) of the cases the oncologist entered a justification in free text at the time of cancellation. The most frequent reason was the need to modify the dose (33% - 82/249). There was 5% (13/249) of justifications with illegible content. Within the justifications charged by oncological pharmacy to put a protocol in the status "In review" (1.2%), 47% was related to an inadequate dose. All the justifications were complete regarding the reason and the instructions for correction by the physician.

4. Discussion

Numerous studies worldwide report the advantages of having a computerized physician order entry for prescribing chemotherapy protocols, supported by the evidence of providing patient safety, comparing with paper prescription [1]. The percentage of use of the CPOE was 93%, which indicates that most of the prescribed protocols used this system. Similarly, a study conducted in Switzerland where only 7% of the total prescriptions were manual and also highlight that the average error rate decreased 22 times [4].

5. Conclusion

Most of the protocols indicated used the CPOE for prescribing chemotherapy protocols implemented, with a rate of use greater than 90%. The rate of protocols intervened by the pharmacist of 1.2% indicates the utility of a CPOE as an error prevention strategy.

Evaluation of Mobile Phone Mortality Risk Score Applications Using Data from the Electronic Medical Records

Nino FIJACKO^{a,1}, Lucija GOSAK^a, Primož KOCKEK^a, Leona CILAR^a, Andrej MARKOTA^b, Gregor ŠTIGLIC^a

^aUniversity of Maribor, Faculty of Health Sciences, Maribor, Slovenia

^bUniversity Medical Centre Maribor, Maribor, Slovenia

Abstract. Various mobile phone apps in the form of medical calculators are available for different prognostic assessments, especially for patients in intensive care units. We performed a systematic review of mobile phone apps in online mobile phone stores to identify apps for mortality risk prediction in intensive care units. Out of 2737 potential mobile phone apps, we included 20 of them in the final content analysis. The most frequently used mortality risk model was Sequential Organ Failure Assessment also known as SOFA. The mobile phone apps were compared based on realistic electronic medical record data. The discrepancies were shown in patients with lower mortality rate. Our results show that this kind of mobile phone apps can be helpful to healthcare professionals and are appropriate for use in clinical practices in most cases.

Keywords. Critical care, mortality, prognostic models, m-health

1. Introduction

In intensive care unit (ICU), healthcare professionals frequently use different prognostic models (PMs) for the quantification of severe physiological derangements in patients. Many PMs are automatically calculated as part of the electronic medical record (EMR) and become a part of health care process. Other can be also used in various mobile phones as mobile phone applications (apps) [1]. In our study, we wanted to identify potentially suitable apps for illness severity prediction in clinical settings and to quantify the characteristics of these apps.

2. Methods

We performed a systematic review of apps in two mobile phone stores (Google Play Store and App Store (iOS)) based on PRISMA recommendations [2]. Using the predictive parameters from the most frequently used PM, we created two different fictional patients with different values using data obtained from the MIMIC III database [3].

¹ University of Maribor, Faculty of health sciences, Žitna street 15, 2000 Maribor, Slovenia; E-mail: nino.fjacko@um.si.

3. Results

Out of 2737, we included 20 apps into detailed analysis among which we identified 38 different PMs. The most commonly used PMs were SOFA and APACHE. The PMs required different types of values for the predictions, such as vital functions (i.e. arterial pressure), laboratory test results (i.e. creatinine) and demographics (i.e. age of the hospitalized patient). Values of both fictional patients were put into SOFA score apps where mortality scores in all apps were consistent, but deviations occurred in the interpretation of mortality, were not.

4. Discussion

Predicting the severity of illness of critically ill patients in the ICU is a comprehensive process that helps physicians anticipate the course of treatment. Based on the data obtained, we found that most apps provide the user with information on which PM was used, since all relevant apps contained information on the scientific research underlying their model. This indicates the quality of PMs, as the calculations in all PMs are uniform and accurate. Discrepancies have occurred in the interpretation of mortality itself, as individual apps interpret the obtained estimate differently. The difference is most obvious in patients with lower mortality rate.

5. Conclusion

In the future, apps for risk prediction will become an important part of healthcare, as they represent a faster and easier access to relevant health information and can be easily used with the patient, allowing us to make a more relevant assessment as the patient's condition can be monitored all the time.

EVENT : A Concept Developed to Improve the Use of EHR by the Nurses

Alain JUNGER

^a *Centre hospitalier Universitaire Vaudois (CHUV – UNIL,
Lausanne, Switzerland)*

Abstract. Context and purpose. The University Hospital of Lausanne has been deploying the patient's electronic record since 2010. In 2014, it was time to abandon the nursing paper documentation file. This represented a user base of 4,000 people to train and accompany during the change process. Design/methodology/approach: We developed the concept of an event as a support for nursing documentation, an empirical process. This project explored a combination of different strategies to improve the quality of care. Research limitations. It is not a research, the concept was new and a theoretical framework was developed. Unfortunately, there was no evaluation undertaken to measure the impact on the users. Practical implications. Today the use of an event helps the nurses to document complex situations and to guarantee the continuity of information. For the future, the question or plan? is to expand the concept to Doctors and other caregivers

Keywords. Business process management, Nursing informatics, Usability, standardized Language, Event, Process modelling

1. Introduction

This poster presents one aspect of the conceptual work whose goal was to describe the nursing activity and roles. The electronic tool acts like a dashboard for a car driver. The concept of EVENT as an episode in which people are involved during an undefined period. These situations might be as different as, daily clinical evaluation, hospital admission, an adverse event, dialysis, surgical intervention, nursing consultation, etc.

To make a simple documentation system that makes the Nursing care complexity visible, prevents a nursing burden being as intuitive as possible

2. Method: Concept of Event and his taxonomy

To document every activity, care, intervention, etc, the work environment must be adapted. In an EHR, this ergonomic facilitation is made possible thanks to the order systems (functionality?) and the related care planning.

The untreated cases are all the situations for which no order is required due to the absence of planning. For example, in the case of a patient admission, a coronary angiography different people are involved, different care and evaluations are made, over a period of time, etc. All these elements are parts of different events.

The taxonomy is in continuous development. The first branch of the taxonomy: Activity contains all the concepts related to the hospital stay. The first domain contains all the movements, the second is dedicated to all types of nursing consultations, the third includes the process related to the management in the operating room, interventional imaging. The fourth is dedicated to administrative activities. The second and third branches integrate the JCAHO taxonomy[2]. These events are dedicated to support the prevention of incidents or the handling of incidents.

We created a documentation model to go out of the focus charting and avoid the model proposed by the Soarian system based on an assessment, nursing diagnoses, interventions and outcomes. ESPOIR [7] for **Event**, Sign & symptoms, Phenomenon, "Objective" (goal), Intervention, Response. This approach is time line oriented. The main change for the nurses was to do bedside documentation in a continuous mode.

3. Results and discussion

The event feature is very effective. Its use has evolved since the beginning of the nursing deployment of the EHR. Today the events implemented are more sophisticated to support nurses in complex clinical situations.

The quality of the documented data has improved beyond that of the old paper age. The different solutions adopted to create the electronic documentation system with the event helped us to face the weakness of the legacy product or paper system? For the future, the question is to expand the functionality to Doctors and other caregivers

Research limitations. It is not a research, even the concept was new, a theoretical framework was developed. Unfortunately, we did not measure the impact on the users.

Experience and Expertise of Teledermatologists with Teledermoscopy: A Systematic Review to Guide Future Practice

Femke VAN SINDEREN^{ab1*}, Esmée TENSEN^{ab*}, Job VAN DER HEIJDEN^a, Leonard WITKAMP^a, Monique JASPERS^b, and Linda PEUTE^b

^aKsyos Health Management Research, Amstelveen, Netherlands

^bAmsterdam UMC, University of Amsterdam, Department of Medical Informatics, Amsterdam Public Health Research Institute, Meibergdreef 9, Amsterdam, Netherlands

* First and second author contributed equally

1. Introduction

Dermatologists' experience with teledermoscopy (TDsc) and accuracy of teleconsultations seem to be related [1]. If so, the diagnostic accuracy of TDsc could be increased by letting more experienced teledermatologists (TDs) assess the teleconsultations [1]. Expertise with assessing dermoscopic pictures is deemed to be more important than image quality in assessing those TDsc consultations accurately [2]. Our aim is to provide an overview on reported characteristics in literature of TDs' expertise in TDsc.

2. Methods

A systematic literature search was conducted using PubMed (MEDLINE), EMBASE (OVID), and Cochrane Skin Review Group with publications until July 2018. Two reviewers (ET and FS) independently evaluated the eligibility of the full original papers focusing on the detection of skin cancer with TDsc using dermoscopic images. The data was extracted according to a pre-defined data extraction sheet. Based on a grounded theory approach, two main themes were determined for further analysis.

3. Results

47 Articles met inclusion criteria, of which 29 articles reported on years of experience and expertise of the TDs assessing the TDsc consultations (Table 1). The grounded theory approach provided insight on expertise with dermoscopy and pigmented lesions, and experience with TDsc. In five of the 24 studies, TDsc consultations were not assessed by dermatologists, e.g. physicians. Six out of 29 studies mentioned that the TDs were board-certified dermatologists without specific characteristics mentioned of

¹ Corresponding author; Femke van Sinderen. Email: f.vansinderen@amsterdamumc.nl.

the obtained certification. Eight out of sixteen studies expressed explicitly the number of years of experience with TDsc, ranging from two until fifteen years. Seven studies rated the experience by general statements, like ‘low level of experience’.

Table 1. Results of the data extraction concerning the teledermatologists’ expertise and experience

Reported:	Expertise (%)	Number of years of experience (%)
Yes	24 (83%)	16 (55%)
No	5 (17%)	13 (45%)
Total	29 (100%)	29 (100%)

4. Discussion

Data was extracted on the experience and expertise of TDs in assessing TDsc consultations. For a majority of the studies, it is unknown what the expertise in dermoscopy and pigmented lesions is, nor the education in (tele)dermatology. Unclearness in assessor expertise indicate to ambiguity in who should assess the TDsc consultations in order to obtain accurate diagnostic outcomes. Future work should focus on guidelines providing insight into the needed experience to be considered an ‘experienced’ TD. Kittler et al. [5] reported an improved diagnostic accuracy for melanoma for experienced TDs suggesting the need of experience and training to perform TDsc. Training for GPs in TDsc has been proposed [6]. Secondly, future work needs to define clear experience scales and develop training guidelines in TDsc, both in studies and in current clinical practices. We will continue this study by focusing on the relation of TDs’ expertise and experience in TDsc with diagnostic outcomes.

5. Conclusion

We conclude that a minority of studies reported on the TDs’ experience and expertise in diagnostic accuracy studies. It is likely that this will influence the diagnostic accuracy.

Experience Story: How Do We Re-Implement What Has Been Implemented?

Melanie CASSARINO^{1a}; Camila GALVAN^a; Juan DESCALZO^a; Elio JEREZ^a;
María SMITH^a; Daniel LUNA^a

a Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract. Since 2017, the Hospital Italiano de Buenos Aires, has a “Workstation on Wheels” project where nurses can access to a mobile application in order to register the drug’s administration, vital signs and complete an early warning assessment scale of the hemodynamic state of the patient. Although the overall objective was to achieve at least 95% drug registration through this system, their use did not remain stable over time. Therefore, it was necessary to create an interdisciplinary team to make a diagnosis of the project situation and reasons for the low use rate. In this process, a re-implementation of the barcoding administration system was carried out, focusing on the nursing staff maintaining the use of the system over time. The aim of this paper is to describe the experience and lessons learned in the process of re-implementing the drug barcoding system at the patient’s bedside.

Keywords. BCMA, implementation, nurses, Workstation on Wheels

1. Introduction

The Hospital Italiano de Buenos Aires (HIBA) is an institution accredited by the Joint Commission International. In 2015 the implementation of the correct drug identification system was carried out through the technique of “barcoding” or reading with a QR code scanner on desktop devices [1]. Then, in 2017, mobile devices (tablets) were incorporated into “Workstation on Wheels” (WOWs) structures with transferable tray [2]. The mobile application is developed with IONIC as source code. This implementation was carried out in various hospitalization sectors, both pediatric and adult, including intensive care and general sectors. Although the overall objective was to achieve at least 95% drug registration through this system, usage did not remain stable over time. Therefore, it was necessary to create an interdisciplinary team to make a situation diagnosis. In this process, a re-implementation of the barcoding administration system (BCMA) was carried out, focusing on the nursing staff maintaining high system use over time. The aim of this paper is to describe the experience and lessons learned in the process of re-implementing the drug barcoding system at the patient’s bedside.

2. Methods

At first, the different areas involved in the BCMA project belonging to the

¹ Corresponding author E-mail: melanie.cassarino@hospitalitaliano.org.ar

Department of Health Informatics (DIS) of the HIBA were convened. Forming a transdisciplinary team of 2 informatic nurses, an informatic physician, two computer technicians, a network technician, a programmer and a designer. Tours around the sectors were organized to inquiry nurses about the reasons behind low system usage.

3. Results

During this process, several strategies were used. On one hand, those oriented to organizational change management and training of professionals, and on the other, strategies related to the adaptation, support and operation of technological equipment.

Regarding change management and training: Incorporation of nursing supervisors to dynamics work, group and individual training, tracking users, training material development, communication lines, help desk, communication and dissemination.

Related to adaptation, support and operation of IT equipment: A technical team consisting of specialists in mobile devices and WiFi networks was put together. They reviewed each HIBA inpatient sector to detect failures. Changes were made to the network, to improve broadcast and connectivity. Software improvements were made together with the development team. Applications to restrict general use of the devices were used, allowing only the BCMA application to run.

4. Conclusions

The management of organizational change is the basis for a large-scale implementation that can modify staff workflow [3]. Communication improvement between parties involved in the project showed great changes at the organizational level. It enabled exchange spaces, allowing them to work more fluently. Empowering both nurses and technicians to form a single work team. It generated a feeling of belonging on both sides. It was very important to generate a communication channel in order to provide users with a space to report failures or malfunctions. It was also important for this channel to allow the tracking of tickets, generating improvements in response times and more durable solutions. With active listening, opportunities for improvement can be detected, such as the potential incorporation of functionalities already implemented in the desktop EHR to the bedside workflow, such as risk assessment [4].

Experiences of National Documentation in Electronic Health Records: The Study Among Occupational Health Nurses

Sari NISSINEN^{a,1}

^a*Finnish Institute of Occupational Health*

Abstract. The Finnish National Patient Data Repository requires all health care professionals to document patient data with a uniform structure. The aim of the study was to gather the experiences of Occupational Health nurses for the usefulness and the ease of use of national patient data structures in electronic health records. The study was carried out in summer 2017. 177 OHNs participated in the study. The respondents felt that the use of the national patient record structures improve the quality of work but doesn't enable to accomplish tasks more quickly. Without patient data and the fluent health information exchange, the patient treatment pathways do not operate properly. The development of patient data structures in EHRs have to be continued.

Keywords. Documentation, Occupational Health Nursing, Occupational Health Care, Electronic Health Records

1. Introduction

The purpose of the eHealth and eSocial Strategy 2020 by the Finnish Ministry of Social Affairs and Health is to provide health care professionals with access to up-to-date patient data and information systems that support their work. In Finland, almost all health care professionals use electronic health records (EHRs). The legislation requires that health care providers save patient data from their own data systems to the national Patient Data Repository (PDR). This requires all health care professionals to document the patient data with a national uniform structure. [1-3] Also the fluent health information exchange among the health care professionals should be done through the national PDR. Thus, the documentation of the patient data has to be executed structurally and consistently. When the data is structured and uniform, its reuse in the annual surveys monitoring health among citizens, and comparison of patient data is also possible. [4, 5] The aim of the study was to gather the experiences of Occupational Health Nurses (OHNs) for the usefulness and the ease of use of national patient data structures in EHRs.

2. Methods

The study was carried out in summer 2017. We used an electronic questionnaire for the data collection. The survey questionnaire was sent to 760 OHNs who were working with pre-selected Occupational Health Services providers. We analyzed the data by using SPSS Statistics 24. The questionnaire consisted of multiple-choice questions

¹ Corresponding Author, Head of Development, Finnish Institute of Occupational Health, Topeliuksenkatu 41 b, 00250 Helsinki, Finland; E-mail: sari.nissinen@ttl.fi.

about usefulness and ease of use of patient record structures. The technology acceptance model (TAM) was used to explain the participants' experiences of perceived usefulness and the ease of use. [6] According to the TAM model, before the use of technology, there is an intention that affects the perceived usefulness (how much the system would enhance job performance) and the perceived ease of use (how easy it is to use the system). The easier a system is to use, the more useful it is perceived to be.

3. Results

177 OHNs participated in the study. Most participants (73%) documented patient data in the patient record during the patient contact, and the rest (27%) after the patient contact. The respondents felt that the use of the national patient record structures improve the quality of work (67%) but doesn't enable to accomplish tasks more quickly (36%). They felt that learning to document with the national patient record structures is easy (81%). It is also easy to remember how to perform documentation tasks using these structures (65%). However, a quite many of the respondents (43%) felt that the documentation with the national patient record structures is rigid and inflexible.

4. Discussion

The patient data is important in health care. Without patient data and the fluent health information exchange, the patient treatment pathways do not operate properly. [4] OHNs play an important role as producers of patient data. In Finland, they make the major of the health check-ups and various health counselling visits. The perceived usefulness and ease of use of technology were identified by the OHNs as important characteristics of the national patient data structure. It is important that national data structures will reduce the burden of OHNs' documentation, rather than increase it. The development of patient data structures in EHRs have to be continued.

5. Conclusions

This study produces new information about national documentation structure that can be used in the development of EHR systems in OHS, and to better serve information exchange among OHNs and the other healthcare professionals. It also enables work ability data to be exchanged in the correct format and in the correct place effectively and reliably.

Exploratory Analysis of Animal Bites Events in the City of Buenos Aires Using Data from Electronic Health Records

Gastón Nicolás QUINTANA^{1a} and Santiago ESTEBAN^a

^aHealth Information System Office, Ministry of Health, Buenos Aires City, Argentina

1. Introduction

Rabies is a viral disease transmitted by rabid animal bites or injuries. It is usually preventable with proper wound care, post-exposure prophylaxis and animal zoonoses programs [1]. In order to face this issue, it is important for the health care system to track animal bites and other animal related injuries. Animal bite information is usually registered in free-text form, within the electronic health record implemented in the public health system of the city of Buenos Aires. Thus, we aimed to develop an NLP pipeline that allowed us to extract animal-bites related information from clinical notes and represent it in a dashboard.

Rabies is estimated to cause 59 000 human deaths annually in over 150 countries. Due to widespread underreporting and uncertain estimates, it is likely that this number is a gross underestimate of the true burden of disease. 99% of rabies cases are dog-mediated and the burden of disease is disproportionately borne by rural poor populations, with approximately half of cases attributable to children under 15 [2].

2. Methods

A regular expression natural language processing pipeline was developed in order to extract the type of animal that caused the injury, the type of lesion it caused, which body part was compromised, geographic location of the event and whether the patient received rabies vaccine treatment. This information was represented in a dashboard for monitoring and evaluation.

3. Results

From January 2017 until December 2019, a total of 18676 animal bite events were registered. Dogs were responsible for nearly 50% of the events. These injuries occurred mainly in the south of the city, mostly in areas characterized by precarious housing. On the other hand, bat bites occurred close to the city center, an area with higher density of apartment buildings. The number of events tends to be regular over the year but winter

¹ Gastón Nicolás Quintana. gastonquintana@buenosaires.gob.ar.

months have the lowest number of cases. Overall, male and female are equally affected but the cases are concentrated in the 0 - 15 age group, involving mostly dog bites.

4. Discussion

Free-text encoding is a very important source of information and physicians prefer it mainly because it is flexible. The development of this pipeline made evident asymmetries not only in geographic case distribution but also in age ranges distribution. This could be useful to create new strategies or improve existing ones.

Figure 1. Plots included in the dashboard

5. Conclusion

We described how we managed to extract clinical information stored in the electronic health records using NLP algorithms. As health information is crucial we believe this is a very useful tool to help the ministry and other areas to design public health strategies.

Exploratory Analysis of Consultation Patterns Prior to the Diagnosis of Depression

Sofia SCIARRETA^{a1} and Santiago ESTEBAN^a

^a*Family and Community Medicine Division, Hospital Italiano, Buenos Aires, Argentina*

Abstract. Depression is frequently underdiagnosed or the diagnosis occurs in late stages, mainly because it usually presents as a paucisymptomatic disorder. Electronic health records (EHRs) are a very useful tool to capture the longitudinal medical history of the patient which may help in diagnosing these patients earlier. We aimed to understand how these patients' consultation patterns are represented in the EHR up until depression diagnosis.

Keywords. Depression, Electronic health records, Depressive Symptoms

1. Introduction

Depression is the most frequent psychiatric medical disorder observed in primary care [1]. The main problem that depression presents is the fact that 50% of the cases are not diagnosed [2][3]. Underdiagnosis is very frequent due to the atypical and varied clinical presentation of depression[3]. Usually, looking at the patients' history and consultation pattern facilitates arriving at a diagnosis. EHRs help to collect and review patient data longitudinally. The objective is to describe the consultation patterns of patients before they are diagnosed with depression at Hospital Italiano de Buenos Aires using data from EHRs.

2. Methods

We manually reviewed a random sample of 600 adult patients over 18 that had at least one depression related code registered in their EHR between 2010 and 2016. 278 had a first diagnosis of depression. We obtained several variables related to healthcare system use. Finally, we explored patient clusters using non-supervised algorithms like k-means and hierarchical clustering. A six cluster solution was found to be the best fit. Clusters were then manually inspected and qualitatively described.

¹ Corresponding author. E-mail: sofia.sciarreta@hospitalitaliano.org.ar

3. Results

Table 1 shows the patients’ characteristics and describes each cluster. Although we statistically obtained a 6 cluster solution, we combined them into 4 according to their main characteristics (Cluster 1, clusters 2 + 3, cluster 4, clusters 5 + 6). Cluster 1: We believe these patients already had a diagnosis of depression, due to the fact that they presented a large number of consultations within a short time of affiliation. In clusters 2+3, there were a large number of consultations to specialties, general medicine, emergency room visits and hospital admissions. They present a pattern of consultations compatible with patients who are underdiagnosed and thus keep seeking care. Cluster 4 and 5+6 comprise most of the sample. Patients in these clusters had most of their visits with their general physician, with different follow up times. They most likely represent patients who take advantage of a primary care centered health system.

Table 1. Patients’ characteristics and description of clusters

Cluster no.	1	2 + 3		4	5 + 6	
n	6	16	4	53	149	50
Age at diagnosis (median [IQR])	72 [58.75, 76.25]	68.50 [62.2, 80]	64.5 [37, 87.5]	65.00 [54, 72]	67.00 [51, 79]	64.5 [46.5, 74]
Women (%)	6 (100.0)	11 (68.8)	4 (100.0)	48 (90.6)	149 (100.0)	0 (0.0)
Seniority	0.30 [0.26, 0.61]	7.47 [1.90, 14.10]	7.95 [4.90, 10.34]	1.57 [0.75, 2.29]	8.27 [5.85, 12.51]	8.89 [6.50, 14.90]
Emergency room visits	0.00 [0.00, 0.00]	0.89 [0.40, 1.30]	1.50 [0.90, 2.48]	0.00 [0.00, 0.82]	0.22 [0.00, 0.60]	0.60 [0.20, 0.98]
Hospital admission	0.00 [0.00, 0.00]	0.00 [0.00, 0.39]	0.50 [0.39, 0.85]	0.00 [0.00, 0.00]	0.00 [0.00, 0.20]	0.00 [0.00, 0.00]
Follow-up years	0.30 [0.26, 0.61]	5.00 [1.90, 5.00]	5.00 [4.46, 5.00]	1.57 [0.75, 2.29]	5.00 [5.00, 5.00]	5.00 [5.00, 5.00]
No. visits per year	203.15 [145.7, 408.7]	62.10 [47.8, 91.2]	42 [37, 47.7]	38.3 [24.3, 64.2]	13.2 [5.4, 22.4]	6.9 [3.5, 16.7]

4. Conclusions

Longitudinal data in the EHR was useful for differentiating clusters of patients with a recent diagnosis of depression.

Exploratory Analysis of Exercise Mentions in Clinical Notes

Nahuel ORCAIZAGUIRRE^{a,1} Santiago ESTEBAN^a

^a*Family and Community Medicine Division, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Abstract. Physical activity has been associated with many positive health outcomes. In this study we explored clinical notes to better understand how physicians record information on this topic.

Keywords. physical activity, electronic health record

1. Introduction

Physical exercise is defined as any body movement that increases energy consumption above the baseline value [1]. It has been associated with improvements in mood [2], quality of sleep, cognitive level, bone density, obesity and type 2 diabetes prevention[3]. Given this, it has become a first line treatment strategy in primary care for many chronic diseases, like cardiovascular disease. For this reason, we set out to analyze clinical notes at Hospital Italiano de Buenos Aires to assess mentions of physical activity recorded.

2. Methods

As a first step we developed a keyword based filter to detect different types of exercise mentions. We evaluated the filter's performance on a random sample of 2047 clinical notes that we manually reviewed and annotated (presence or absence of physical activity mentions). Afterwards, we applied the filter and obtained a random sample of 750 clinical notes which we manually reviewed to identify which types of exercise patients report doing, which ones physicians prescribe and why they prescribe them to their patients.

3. Results

After manual review, we detected that 157 out of 2047 clinical notes had physical activity mentions (7.7%, 95% Confidence interval (CI) 6.59 - 8.9%). The keyword

¹ Dr. Nahuel Orcaizaguirre, Hospital Italiano Buenos Aires, Pres.Tte.Gral. Juan Domingo Peron 4190, Buenos Aires, Argentina. Email: nahuel.orcaizaguirre@hospitalitaliano.org.ar.

filter yielded a sensitivity of 0.977 (95% CI 0.910 - 0.996), positive predictive value of 0.840 (95% CI 0.750 - 0.903) and F1 score of 0.903 (95% CI 0.857 - 0.942).

After reviewing the 750 clinical notes we observed that physicians mostly (68%) prescribe physical activity in a very generic way (recommendations of 'starting physical activity' or 'joining a gym'). Less frequently (32%), they specify a certain type of activity, usually walking (23%). In most cases there was not enough information as to why a particular type of physical activity had been prescribed. Regarding the reasons why physical activity is being prescribed, the main ones were cardiovascular prevention (includes the treatment of risk factors such as hypertension or diabetes, 42%), treating obesity (25%) and improving general body aches (11%).

4. Discussion

Our results indicate that physical activity is seldom registered in the clinical notes and when it is, there is a lack of information on what it is being prescribed for. We believe that non-pharmaceutical treatments should be registered as rigorously as pharmaceutical treatments, since they are part of many treatment plans. Not having this information available hinders the decision-making process in future consultations.

Furthermore, we see that there is not much variety in the activities suggested by medical professionals. It would be interesting to analyze in the future if this can be related to limited knowledge about the different options available.

5. Conclusion

In our study, physical activity mentions were present in a small proportion of clinical notes in the outpatient setting. Furthermore, information regarding the cause for prescription was scarce. We emphasize the importance of recording non-pharmaceutical treatments rigorously.

^cFujita Health University

Abstract. In this paper, we propose feature extraction method for prediction model for at the early stage of diabetic kidney disease (DKD) progression. DKD needs continuous treatment; however, a hospital visit interval of a patient at the early stage of DKD is normally from one month to three months, and this is not a short time period. Therefore it makes difficult to apply sophisticated approaches such as using convolutional neural networks because of the data limitation. The propose method uses with hierarchical clustering that can estimate a suitable interval for grouping inputted sequences. We evaluate the proposed method with a real-EMR dataset that consists of 30,810 patient records and conclude that the proposed method outperforms the baseline methods derived from related work.

Keywords. disease risk prediction model, diabetic kidney disease

1. Introduction

We constructed a risk prediction model for diabetic kidney disease (DKD) that receives the medical events of a patient in the past 180 days and predicts whether the patient will stay at the 1st stage after 180 days. A patient at the early stage of DKD needs continuous treatment; however, a hospital visit interval is from one month to three months, and this is not a short period. We focused on this issue, and the proposed method derives time series variation with hierarchical clustering that can estimate a suitable interval for grouping inputted sequences.

The number of studies on risk prediction models has increased and most of the studies applied logistic regression or cox regression to the latest medical events. Some studies focuses on patients that frequently visit a hospital, so records with many medical events in a certain period of time are available [1][2] and use CNN to distill a time series variation of a given patient.

The proposed method transforms a value sequence into groups on the basis of the result of the hierarchical clustering for a corresponding timestamp sequence. We use the hierarchical clustering method that has the constraint not on the number of the clusters but on the distances among the clusters. Then, we derive the time series variation from

¹E-mail: moonoo@jp.ibm.com

Table 1. The AUC in the prediction for the stage of DKD of the patient after 180 days. “LR” stands for the logistic regression.

ID	Model	AUC	ID	Model	AUC
1	LR without time series variation	0.625	4	CNN #1 (interval 30 days)	0.632
2	LR with time series variation	0.722	5	CNN #2 (interval 14 days)	0.660
3	CNN #1 (interval 14 days)	0.666	6	CNN #2 (interval 30 days)	0.635

the group. For example, we calculate the averaged value and the standard deviation from the averaged cluster’s values. The key factor is the hierarchical clustering that can estimate a suitable interval for grouping inputted sequences. We use logistic regression as a statistical model for the prediction because logistic regression can provide interpretable results. Interpretation is one of the important factors in the field of medical informatics.

2. Results and Discussion

We evaluate the proposed method with a real-EMR dataset from a Japanese hospital. We collected the medical history of a patient at the 1st stage. The number of patients is 30,810, where half of the patients remain at the 1st stage after 180 days. We focus on 12 kinds of laboratory tests as feature sets on, for example, uric protein and eGFR.

We conducted a 5-fold cross-validation test in the experiment and measured the AUC, which is the standard evaluation metric for a classification problem. And we used the baselines, the first of which is a logistic regression that handles the latest values of the feature sets and does not handle the time series variations that the proposed method creates. The other baselines are two kinds of CNNs that consist of 5 layers and handle feature matrices created in a previous work [1] [2]. We created two kinds of feature matrices created with different the interval for CNNs, 14 days and 30 days.

Table 1 shows the experimental results. The best performance is 0.722, which was achieved by the logistic regression with the time series variation that the proposed method creates. The experimental results point to the following conclusion: (1) understanding the time series variation improves the prediction performance of the risk prediction model of diabetic nephropathy and (2) the proposed method outperforms the baselines. The first conclusion is reached on the basis of the comparison between the ID 1 result and the others; the AUC of ID 1 is lowest and is derived from the logistic regression without the time series variations. The second conclusion is reached on the basis of the comparison between the ID 2 result and the others. The ineffectiveness of CNN for this task is caused by the missing value in the feature matrix. A low frequency of hospital visits causes the missing value in the feature matrix for CNN.

FHIR Driven Self-Management Support System for Diabetes

Dietmar GLACHS^{a1}, Tuncay NAMLI, Oliver JUNG^a, Felix STROHMEIER^a, Manuela PLOESSNIG^a and Gustavo RODRIGUEZ^c

^aSalzburg Research Forschungsgesellschaft mbH, Salzburg, Austria

^ciHealthLabs Europe SAS, France

Abstract. The number of people with diabetes is increasing in every European country and as with all chronic diseases, coping with diabetes is a long-term process. Self-Management and supporting behaviour change are aspects when dealing with diabetes. The POWER2DM² system combines treatment planning and self-management activities by providing interventions to change a patient's lifestyle towards a healthier, diabetes-appropriate life. FHIR³ allows for data exchange.

Keywords. decision support systems, self-management, behaviour change

1. Introduction

In this paper, we introduce the Self-Management Support System (SMSS) for Type 1 and Type 2 diabetes patients based on the Personal Data Store (PDS), a fully FHIR compliant data repository providing electronic health records. Empowering patients [1] by integrating them to a greater extent with their own healthcare process is the overall target. Disease management becomes an integrated part of their life.

2. Method

Self-Management Support is implemented as a guided iterative workflow cycle, typically on a weekly basis. Treatment plans are usually generic and span longer periods of time. Patients are requested to adopt the practitioner's treatment plans into personal goals and to plan activities he or she wants to accomplish within a shorter period of time. Increasing the patient's adherence to the personal action plan is achieved by providing interventions based on Behaviour Change Techniques [2]. Basically, the workflow consists of four main steps as shown in Figure 1. First the patient specifies self-management *Goals* and relates them to the practitioners' treatment plan.

Secondly, *Actions* like tasks and activities are planned with a Calendar. Again, tasks and activities are related to self-management and treatment goals. In the *Monitoring*

² Funded by the EU Horizon 2020 research and innovation programme under grant agreement No 689444

³ "Fast Healthcare Interoperability Resources" (<http://hl7.org/fhir>).

phase, blood glucose, blood pressure and body weight are recorded with devices. Activities such as medication intake, physical exercises, meals are recorded manually. It is also possible to keep a diary for problems, mood, sleep and stress. Finally, with the Periodic Review, the recorded data is *evaluated* and performance *feedback* is provided. For each of the review categories, positive reinforcement messages [3] or recommendations for the next action plan cycle are given. In [4], the intervention mechanisms are explained in detail.

Figure 1. Patient Empowerment Workflow

Data is maintained FHIR compliant with the PDS while ensuring interoperability. 39 FHIR “Profiles” and FHIR “Extensions” customize basic FHIR resources and contribute SMSS specific data elements [5]. A detailed architecture of the POWER2DM system is given in [6]. The FHIR profiles are available at Simplifier.net⁴.

3. Conclusion

The Self-Management Support System supporting behaviour change is currently evaluated in pilot applications in a production environment with 230 patients (115 type-1, 115 type-2) in the Netherlands and in Spain. The trial evaluates the acceptance rate and effectiveness of the presented interventions. Results are expected by the end of the pilot applications. A test system is also available and adjustable to other chronic diseases.

GDPR Compliant Blockchain and Distributed Ledger Technologies in the Health Sector

Anton HASSELGREN ^{a,1}, and Katina KRALEVSKA ^b, Danilo GLIGOROSKI ^b and Arild FAXVAAG ^a

^a*Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, NTNU- Norwegian University of Science and Technology, Trondheim, Norway*

^b*Department of Information Security and Communication Technologies, Faculty of Information Technology and Electrical Engineering, NTNU-Norwegian University of Science and Technology Trondheim, Norway*

Keywords. Blockchain, Distributed Ledger Technology, GDPR, Health Data, Protected Health Information

1. Introduction

In 2018, The European Union instituted the General Data Protection Regulation (GDPR), which regulates the collection, processing, and securing of personal data, including protected health information (PHI). As detailed by the European Union Blockchain Observatory and Forum [1], in principle, there are no contradictions between the goals of GDPR and Distributed Ledger Technologies (DLT). However, there seems to be at least three areas in which GDPR still does not offer enough clarity about how real-world DLT applications for the health sector should be developed. These areas include (1) accountability and roles (eg, how to identify a data controller in a public DLT), (2) anonymization of personal data (eg, what techniques are sufficient to anonymize personal data to the point where the resulting output can potentially be stored in a DLT), and (3) GDPR rights conflicts (eg, how to rectify or remove personal data that are recorded in a DLT that is immutable by nature, or who is responsible for requesting and managing the “freely, specific, informed, and unambiguous” consent from a data subject, especially if the data controller is not specified) [2]. With regards to anonymization of personal data, it is clear that GDPR does not apply to anonymized data and that this type of information can be stored on the DLT. However, what qualifies as anonymized is still not clear. The only indication today is that it must be irreversibly impossible to identify an individual through any of the means “reasonably likely to be used” [3]. The objective of this study is to dissect the various designs of DTL and look for GDPR compliance for the different components in established or proposed blockchain/DTL applications that deals with health data.

¹ Corresponding Author, Mellomila 69, 7018 Trondheim, Norway; E-mail: anton.hasselgren@ntnu.no

2. Method

A comprehensive review over the current GDPR official documents and other reports that touch upon the subject, including the report developed by the EU blockchain Observatory and Forum [1]. Furthermore, a summary of peer-reviewed publications under the topic and retrieval of white papers for proposed applications in the health sector. Literature reviews of high quality that summarize the current state-of-art and state-of-knowledge should be explored. Summarize the key aspect of the reviewed literature and the key components of blockchain/DTL will be based on peer-reviewed summaries/literature reviews.

3. Results

Our preliminary results indicate that there are several areas where blockchain/DTL in the health sector may face challenges when it comes to GDPR. More specifically, a public blockchain that contains on-chain data related to an individual's health, faces serious challenges when guaranteeing the anonymization of that data.

4. Discussion

There are clear indications that carefully considerations should be undertaken when designing a blockchain infrastructure that deals with health data, to comply with the current GDPR. As previous research shows, the developer of a blockchain system have several important design decisions to make that affect the privacy, access and accountability of the system. It is of high importance to consider the GDPR and especially the three areas mention in the introduction.

5. Conclusion

How blockchain and DTL comply with current regulations for health data have been suggested to be one main barrier for implementation of this technologies in the health sector. Our preliminary result shows that when certain design choices are made, blockchains and DTL for the health sector may not only comply with the current GDPR but will contribute to reinforce the regulations.

^c*Department for anesthesiology, surgical intensive care medicine and pain therapy, University Hospital of Gießen and Marburg, Gießen*

^d*Department for cardio surgery, University Hospital of Gießen and Marburg, Gießen*

Abstract. The University Hospital of Gießen and Marburg (UKGM), Gießen, Germany participates in a country wide nosocomial infections surveillance project on intensive care units (ICU) called KISS. KISS data must be gathered daily and is comprised of detailed clinical data like patient movements, ward utilization, presence of central venous and urinary catheters and types of artificial respiration. This happens for all of the 10 ICU's at UKGM Gießen and proved to be very tedious and time consuming for the institute for hospital hygiene. The goal of this project was the automated generation of the KISS reports from routinely collected data in the patient data management system (PDMS). The results show that this is largely feasible without changing the documentation habits of physicians and nurses.

Keywords. PDMS, hospital hygiene, nosocomial infections, infection surveillance

1. Introduction

The University Hospital of Gießen and Marburg (UKGM), Gießen, Germany participates in a country wide nosocomial infections surveillance project on intensive care units (ICU) called KISS [1]. All participants of the KISS study must provide a set of clinical data items on a daily basis. The items are comprised of counters for patient movements, ward utilization, presence of central venous and urinary catheters and types of artificial respiration. They are collected for all of the 10 ICU's at UKGM Gießen. This is a very tedious and time-consuming process for the members of the institute for hospital hygiene. The goal of this project was to derive automatically all parameters of the KISS report from routinely collected data in the patient data management system (PDMS). This should happen without changing the established documentation habits on the wards.

2. Material and Methods

The University Hospital of Gießen and Marburg (UKGM), Gießen, Germany operates a patient data management system (PDMS) on all intensive care units (ICU's) and intermediate care units (IMC's) since 1999 [2]. The documentation is based on a controlled vocabulary that covers all aspects of intensive care including application of intravenous and urinary catheters, applied drugs and presence and type of artificial respiration. A background application has been developed, that routinely checks the PDMS data for the presence of information regarding the KISS study parameters. This is accomplished by checking the presence of a set of device related concepts from the vocabulary. The analysis is done for the complete course of a patient stay to keep track of application and removal of the different types of catheters. All results are collected in a separate hygiene database. The content of the hygiene database is displayed with an ASP.NET Web-Application. The GUI layout resembles the layout of the KISS data entry form and therefore allows for seamless copy and paste of information.

3. Results

Development started in early 2018. Since October 2018 the system is used for cross checks of the manually collected data which acts as a gold standard. Quality checks and optimizations are currently applied separate for every clinical department. Data shows a sensitivity of 1.0 for detection of admissions and discharges, 0.95 for urinary catheters and 0.9 for central venous catheters and artificial respiration. Specificity for admissions and discharges is 0.8 and 0.9 for urinary catheters, central venous catheters and artificial respiration. Incomplete documentation of device application or removal has been detected as the main reason for failure of the automated process. Additional analysis of the clinical context e.g. balance data for urinary catheters, has proven to be a valuable source of information to cope with this documentation deficits.

4. Discussion

The developed application allows for a great amount of time saving for the members of the institute for hospital hygiene. It removes the need to manually extract data from clinical charts on a daily basis which proves to be an error prone and tedious process.

In future the data extraction system will be enhanced to extract more data which could then be used to act as an early warning system for nosocomial infections.

Great Help for Small People – The Development of a Children's Emergency App

Judith BORN^{a,1}, Christina OHLMEIER^a, Jasmina KIS^b, Ralf SICK^c, Jörg OBERFELD^a
and Christian JUHRA^a

^aUniversity Hospital Muenster, Germany

^bHELIOS S. Josefs Hospital Bochum, Germany

^cSt. Johns Ambulance Service, Germany

Abstract. In order to assist parents in providing rapid first aid to children in case of emergency, a mobile emergency application was developed. The children's emergency app works with intuitive graphics and checklists and combines several functions such as tips for preventing accidents, easy-to-understand instructions for first-aid actions and a search function for the next pediatrician or hospital. This app is not intended to be a substitute, but rather an addition to first aid courses.

Keywords. Mobile apps, children's health, first aid, prevention

1. Introduction

Accidents are one of the highest risks to children's health. The German Federal Ministry of Health estimates that in Germany medical care is given to around 1.7 million children who experience accidental injuries each year [1]. An emergency of one's own child is one of the greatest worries for any parent. When health emergencies occur and seconds count, adults must take the right actions to save lives. They need to feel confident within the situation to be able to do so, but in fact many people are afraid to do something wrong in case of an emergency [2]. For this reason the St. Johns Ambulance Service Germany, the BARMER health insurance, the mobile application development company Opwoco and the University Hospital Muenster developed an mobile application, which is intended to help parents, tutors or teachers to initiate necessary steps in emergency situations until paramedics or doctors can intervene.

2. Method

The cornerstone for the app was placed within a project called MARIKA, which was funded by the European Union and the Federal Ministry of Health, Emancipation, Care and Aging of North-Rhine Westphalia. Within this project a survey on user interests and needs in the field of mobile health applications was conducted among 316 patients and accompanying persons at the University Hospital of Muenster [3]. On the basis of these findings and on the basis of the guidelines of the European and German

¹ Corresponding Author: Judith Born, University Hospital of Muenster, Hüfferstraße 73-79, 48149 Münster, E-Mail: judith.born@ukmuenster.de

Resuscitation Councils as well as the experiences of the nationwide "First Aid for Children" courses of the St. Johns, the children's emergency app was developed.

As a database for the location-based search function for pediatric and surgical ambulances, the quality reports of the clinics were used. These are published annually by all clinics in Germany.

3. Results

The children's emergency app meets all data protection requirements of the Federal Data Protection Act in Germany and can be used free of charge on Android and iOS. It works with intuitive graphics and checklists, so it is easy to understand and intuitive to use and combines several important functions:

- search for the next pediatrician, hospital, etc.
- setting up an emergency call
- easy-to-understand instructions for first-aid actions
- tips for preventing childhood accidents
- individually fillable address book for important medical numbers

4. Discussion

The number of downloads (107.688 downloads within two years) and ratings on the download platforms indicate a high user acceptance. The app is refined continuously, so in the beginning of 2019 an updated version was provided, which was extended by the topic "childhood diseases". In addition, the app has been provided with a new feedback function. Since the app is only available in German so far, the translation into different languages will also be considered.

5. Conclusion

The children's emergency app is not a substitute, but a valuable addition to first aid courses on the child. Even with the newly integrated feedback function, the greatest challenge for the developers remains to keep the contact data for all hospitals, paediatricians and pharmacies up to date, as there is a lack of a central and current database for all health care providers in Germany.

Greek Hospitals Web Accessibility

Andriana MAGDALINO^{a,1} and John MANTAS^a

^aNational and Kapodistrian university of Athens, Greece

Abstract. Even though Internet is an exciting technological tool, it requires innovative design to be accessible to everyone, including people with disabilities. The purpose of the present work is to evaluate the accessibility of the web sites of the hospitals which are under the Greek Ministry of Health and belong in the first Health Region using a free WCAG 2.0 and Section 508 Web Accessibility Check software. An observation of the websites along with the software showed that no website meets the W3C criteria of accessibility.

Keywords. Accessibility, website, disability

1. Introduction

Internet access equality is important because of the impact on peoples' health and on society [3]. At the social level, Internet accessibility and use is associated with increased citizens' trust, interpersonal trust and life satisfaction [4]. People with disabilities seem to be facing a significant digital divide having access to different types of services [1], [9], [11]. People with disability are usually not independent with health information retrieval [2]. More precisely, people with vision impairment tend to use screen readers to browse the Web. For this purpose, web sites elements must be accessible and readable from screen readers [8]. The Web Content Accessibility Guidelines (WCAG) [7] were developed by the World Wide Web Consortium (W3C) [5] and are widely accepted as standards for digital accessibility [10]. The purpose of this article is to evaluate the web accessibility of the public hospitals which are under the Ministry of Health [6] and belong in the first Health Region in Greece.

2. Methods

Twenty five hospitals that belong to the first Health Region were identified from the official website of the Ministry of Health and twenty one of them had website. The free WCAG 2.0 and Section 508 Web Accessibility Check tool [5] was used to automatically scan the websites and evaluate accessibility based on the WCAG 2.0 criteria. Website accessibility issues were distributed in the following categories: Font, Images, Tables, Headings, Links, Colours, Labels, Pop ups, Tags, HTML element missing, Sitemap missing. Hospitals with one or more accessibility issues did not meet the W3C criteria and they were rated as non accessible.

¹ Corresponding Author: Andriana Magdalino, National and Kapodistrian University of Athens, Papadimantopoulou 123, Athens, Greece; E-mail: alfami@nurs.uoa.gr.

3. Results

Twenty one hospital websites were evaluated giving the following results: 29% of the hospital websites had Font size issues. 72% of the hospital websites had images related issues such as images with empty alternate text, images inside an anchor tag without alternate text, animated images and images without alternate text. 48% of the hospital websites had issues Tables. 38% of the hospital websites had issues with missing or empty Headings. All hospitals websites had issues with empty links or missing skip links and links with ambiguous link text. Moreover elements to be using an event handler such as on click to emulate a link were found. 33% of the hospital websites had issues with the colour background. More precisely, an element was found to not have a contrast ratio of at least 4.5:1 between the foreground and background colours and no buttons for background colour alteration and letter size alteration was found. 29% of the hospital websites had a form field found to be missing labels. 76% of the hospital websites had issues with pop up windows. 38% of the hospital websites had issues with the tags. 48% of the hospital websites HTML element was missing. 38% of the hospital websites had no sitemap. No hospital website met all the WCAG 2.0 criteria.

4. Conclusions

The main issues found in the majority of hospitals websites were related to images, links and pop up windows. More specifically missing skip links, untitled tables, and images without alternate text were identified. The hospital websites included in this work do not meet the WCAG 2.0 specifications and therefore cannot be considered accessible. These hospital websites should be updated in order to comply with accessibility standards.

Health Facility Ownership Type and Performance on HIV Indicator Data Reporting in Kenya

Milka B. GESICHO^{a,b,1}, Ankica BABIC^{a,c} and Martin C. WERE^{d,b}

^aDepartment of Information Science and Media Studies, University of Bergen, Norway

^bInstitute of Biomedical Informatics, Moi University, Kenya

^cDepartment of Biomedical Engineering, Linköping University, Sweden

^dVanderbilt University Medical Center, USA

Abstract. In low- and middle-income countries, private and public facilities tend to have highly variable characteristics, which might affect their performance in meeting reporting requirements mandated by ministries of health. There is conflicting evidence on which facility type performs better across various care dimensions, and only few studies exist to evaluate relative performance around nationally-mandated indicator reporting to Ministries of Health. In this study, we evaluated the relationship between facility ownership type and performance on HIV indicator data reporting, using the case of Kenya. We conducted Mann-Whitney U tests using HIV indicator data extracted from years 2011 to 2018 for all the counties in Kenya, from the District Health Information Software 2 (DHIS2). Results from the study reveal that public facilities have statistically significant better performance compared to private facilities, with an exception of year 2017 in reporting of counselling and testing, and prevention of mother-to-child transmission indicator categories.

Keywords. HIV-indicator reporting, health facility, ownership, performance,

1. Introduction

In most LMICs, health facilities are required by the Ministries of Health (MoH) to report on various HIV indicators to aid in monitoring and evaluation of HIV programs, advocacy, policy and decision-making. In general, reported indicators are expected to be timely, accurate and complete. Few studies exist that rigorously evaluate differences in performance, and reviews of performance by facility-type have often led to conflicting conclusions[1]. Ownership of health facilities has the potential to affect the performance of health facilities at meeting these HIV reporting requirements, yet rigorous evaluations on relationship between facility type and HIV indicator reporting are limited. With increasing use of national-level centralized electronic HIV-indicator data aggregation and reporting systems such as the District Health Information Software 2 (DHIS2), data now exists in several LMICs for these evaluations. The aim of this study is to establish the relationship of health facility ownership type with ability to meet HIV indicator

¹ Corresponding Author. Milka Gesicho, E-mail: milcagesicho@gmail.com

reporting requirements, using the case study of Kenya. The reporting requirements assessed in this study are completeness and timeliness in facility reporting.

2. Method

A retrospective observational study was conducted in order to identify the relationship between facility type and performance on HIV indicator reporting in Kenya. Reporting data used was from years 2011-2018. From DHIS2, we extracted the following HIV indicator categories based on Kenya's MoH731² summary form: (i) HIV Counseling and Testing (CT), (ii) Prevention of Mother-to-child Transmission (PMTCT) of HIV, (iii) Care and Treatment (CRT), (iv) Voluntary Medical Male Circumcision (VMMC), (v) Post-Exposure Prophylaxis (PEP), and (vi) Blood Safety (BS). Mann-Whitney U tests were conducted in order to compare the two ownership types.

3. Results

There were no statistical significances in performance in reporting of VMMC and BS indicators, which are peripherally associated with the HIV programs. Statistically significant results in performance, and mean ranks for both private and public varied in the different indicators. Performance in completeness and timeliness also varied by year, with public institutions performing better across multiple indicators with the exception of year 2017 in reporting of HIV CT, PMTC indicators.

4. Discussion

Our study only looks at yearly dimensions, but further analyses could be done by county, facility level, and facility type. This work highlights the key potential of how aggregate reporting data can be used to inform decision-making. Qualitative studies can further help highlight factors promoting or hindering quality indicator reporting

5. Conclusion

In this study, we observed a general trend of public facilities in outperforming private facilities in timeliness and completeness of health facility reporting of nationally-mandated HIV indicators.

Hierarchical Clustering for Image Classification in Dermatology: Towards Mobile Deploying

Miruna D. CIULU^a, Stefan HOLBAN^a, and Diana LUNGEANU^{b,1}

^a*Faculty of Computer Science, Polytechnic University of Timisoara, Romania*

^b*Department of Functional Sciences, University of Medicine and Pharmacy Timisoara, Romania*

Abstract. In the context of increasing interest in computer-assisted diagnosis for skin lesion images and mobile applications to be used in real life settings, we propose a combined desktop-smartphone solution for dermatological image classification. Hierarchical agglomerative and divisive clustering are both implemented as methods of cluster analysis, with the RGB color histogram as descriptor for a global image analysis. The cosine similarity is employed for classifying the query image in one of the available clusters, characterized by their centroids. The solution has been tested with a public database of dermoscopic images, with an overall accuracy of 0.73, 95%CI (0.58;0.85).

Keywords. Decision support, skin cancer, melanoma, color histogram analysis, artificial intelligence

1. Introduction

Skin cancer is an increasingly worrying medical problem and artificial intelligence solutions have proved increasing performance in the recent approaches for cancer diagnosis: clustering in general or for dermatology in particular, support-vector machines, deep learning, or even combinations with successful human-machine partnerships [1,2]. We propose a combined approach of desktop-mobile applications, employing hierarchical clustering for image classification. This is an ongoing work we have tested with a research database of annotated dermoscopic images, PH2 [3].

2. Methods and implementation

Two types of hierarchical clustering methods were implemented: (a) agglomerative bottom-up approach, with three linkage criteria (minimum or single-linkage; maximum or complete-linkage; and average linkage); (b) divisive top-down approach. Two metrics to measure the dissimilarity between the sets of images were implemented: the Euclidean and the Manhattan distances. Figure 1 shows the structure of the application.

¹ Corresponding Author. Diana LUNGEANU, Department of Functional Sciences, University of Medicine and Pharmacy, P-ta E. Murgu 2, 300041 Timisoara, Romania; E-mail: dlungeanu@umft.ro; Tel/Fax +40-256-490288

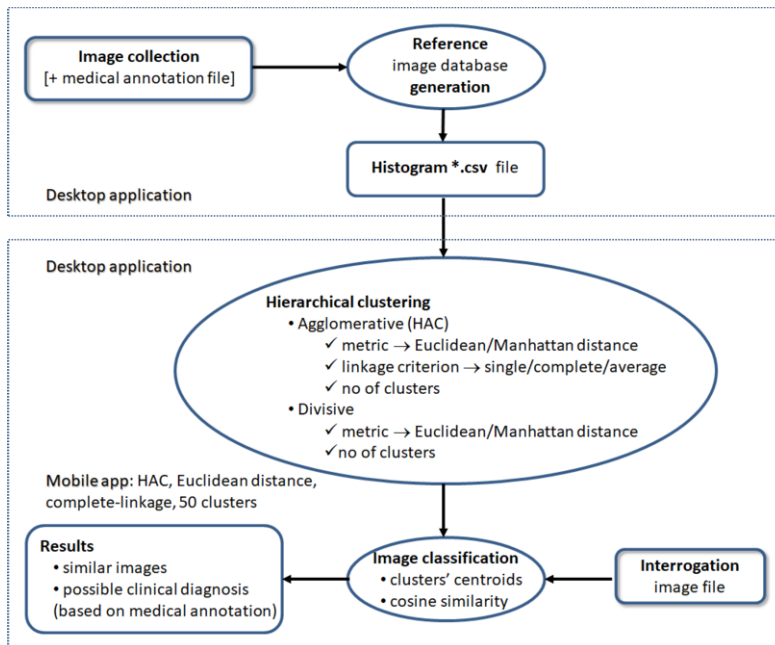

Figure 1. Implementation of the hierarchical clustering: the reference database and histogram file are generated by the desktop application, while the clustering and classification can be performed within the desktop (full options) or mobile (reduced options) application.

3. Results, discussion, and conclusion

The performance assessment was four-folded: (i) hierarchical agglomerative (HAC) vs. divisive clustering; (ii) Euclidean vs. Manhattan distance; (iii) no of clusters; (iv) HAC-related three linkage criteria. The overall results were: sensitivity=0.8, 95%CI (0.61;0.92); specificity=0.6, 95%CI (0.33;0.83); accuracy=0.73, 95%CI (0.58;0.85).

The combined approach we propose merges the advantages of desktop applications' computational power and mobile implementations' friendliness towards a large variety of potential users. The hierarchical clustering presented herewith only uses the global color properties of images, so the classification is generalizable to both dermoscopic and general dermatological images.

How to Decide upon Nursing Technologies – A Participation-Based Approach

Jörn KRÜCKEBERG^{a,1}, Ronny KLAUWUNN^b, Inessa FUGE^a,
Reza MAZHARI^c, Regina SCHMEER^c and Nicole HECHTEL^a

^a*Peter L. Reichertz Institute for Medical Informatics, University of Braunschweig –
Institute of Technology and Hannover Medical School*

^b*Institute for Epidemiology, Social Medicine and Health Systems Research, Hannover
Medical School*

^c*Department of Nursing, Nursing Science, Hannover Medical School*

Abstract. This study describes an approach to support decisions on the acquisition of innovative nursing technologies. The approach focusses a participatory design that involves nursing staff from the beginning of the process and aims at achieving positive results regarding identification with the decision of implementation and use of technologies by nursing staff.

Keywords. Nursing technology, participatory management, nursing informatics

1. Introduction

Within the project *center of implementing nursing care innovations* (PPZ Hannover)² innovative technologies are being integrated into everyday nursing work life to support nursing staff and improve patient care on a trauma surgery ward of Hannover Medical School. In order to involve the nursing staff into the research project, a participatory introduction concept was designed and implemented.

2. Methods

Next to an extensive baseline investigation in a mixed methods design [1], the participatory approach uses results from workshops with nursing staff to assess the current work situation on the ward and to derive the need for technical solutions [2]. These results again lead to workshops where innovative nursing technologies are presented and discussed with all nurses of the ward. In the reported workshop a mobilization system for prophylaxis of decubitus ulcer and a robotic companion for dementia care were presented. Instruments for data collection in this setting were

¹ Corresponding Author: E-mail: joern.krueckeberg@plri.de

² Funded by the German Ministry of Education and Research, grant number: 16SV7892K

- guideline-based discussions on usefulness
- a modified questionnaire on the suitability for use [3].

The discussion was documented and analyzed following qualitative content analysis. The results of the questionnaire were calculated for two categories and a total score on defined suitability scores.

3. Results

Both nursing technologies are believed to reduce burdens on patients and nursing staff, while concerns differed between technologies as stated by the nursing staff. Possible improvements for a better adaptation on local conditions were discussed as well. The results of the questionnaire on suitability state a clear tendency for both the products being rated “very suitable” for nursing work life (see table 1). Even though the robotic companion received some criticism in general and in specific aspects of suitability.

Table 1. Summarized results of questionnaire on suitability for use

	General suitability	Specific suitability		
Categories	functionality usability workflow compatibility product quality patient's well-being	power supply alarms (MS) screen (MS) mobility consumables (RC) processing	Suitability for use / total score	
Robotic Companion (RC) n = 15	14 % (3)	19 % (4)	9 % (2)	not suitable
	22 % (4)	31 % (5)	34 % (6)	limited suitable
	64 % (8)	50 % (6)	57 % (7)	very suitable
Mobilization System (MS) n = 14	0 %	12 % (3)	5 % (1)	not suitable
	11 % (2)	33 % (5)	31 % (5)	limited suitable
	89 % (12)	55 % (6)	64 % (8)	very suitable

4. Discussion

The mix of quantitative and qualitative instruments seem to be an appropriate and reliable method to assess suitability of use for nursing technologies. Results of the discussion are matching the results of the questionnaire. The presentation of these results to nursing staff is necessary to comply with the participatory process and might lead to greater identification with the decision of implementation and use of technologies.

How to Extract and Explore Big Data for Fraud Detection in the Healthcare Sector: The EOPYY Case Study

Spiros GEORGAKOPOULOS^{a,1}, Parisi GALLOS^a and Vassilis PLAGIANAKOS^{a,b}

^a *Hellenic National Organization for the Provision of Health Services, Greece*

^b *European Healthcare Fraud and Corruption Network, Belgium*

Abstract. Big Data technologies can contribute to medical fraud detection. The aim of this paper is to present the methodological approach of the Hellenic National Organization for the Provision of Health Services (EOPYY) in data analysis to detect financial or medical fraud. To analyze the data for fraud detection, a selection of prescription data from the year 2018 were examined. The Local Correlation Integral algorithm was applied to detect any outliers on the dataset. The results revealed that 7 out of 879 cases could be characterized as outliers. These outliers must be further investigated to determine if they have been associated with fraud. According to the results of this study, this outliers' detection approach can support and help the fraud detection process conducted by the auditing services in Healthcare sector.

Keywords. Fraud Detection, Healthcare, Big Data, Outlier Detection

1. Introduction

Big Data Technologies have been applied in Healthcare sector providing significant advantages on both the quality of the healthcare services and the control of the cost [1]. According to the international literature, the ability to detect fraud in medical claims seems to be a major asset on the expenditure control [2]. Specific Big Data analytic techniques can lead to effective fraud detection in the health domain [3]. The aim of this paper is to present by an example the methodological approach of the Hellenic National Organization for the Provision of Health Services (EOPYY) in data analysis to detect financial or medical fraud in claims.

2. The EOPYY Case Study

EOPYY carries the healthcare provision and claims data of all the Greek citizens. Currently, the databases size is approximately 5 TB with a data increase rate of 140 GB per month, creating a valuable Big Data repository for medical claims. To analyze the data for fraud detection, the 2018 prescription data of the following product categories

¹Corresponding Author, Spiros Georgakopoulos, MSc, PhD, Advisor to the President of the Hellenic National Organization for the Provision of Health Services, Apostolou Pavlou 12, Marousi, Greece; E-mail: spirosgorg@uth.gr.

were extracted (more than 4,000,000 entries) from the above databases: (i) Products and Supplies for Diabetes Management, (ii) Catheters, (iii) Medical Pads, and (iv) Special Nutrition Products and Supplements. For each of the above case, the date of the prescription, the prescriber, the specialty of the prescriber, the patient's social security number, the product name, the category of the product, the product provider, and the location of the provider were selected. After data selection, appropriate anonymization techniques (SHA-1 algorithm for one-way data encryption) were applied to comply with GDPR requirements before the data analysis. The aforementioned raw data were transformed in a manner to describe new features for each product based on the number of the cases. Specifically, the following features were calculated: (i) the number of the prescriptions, (ii) the number of patients who received each product, (iii) the number of prescribers who prescribe each product, (iv) the number of prescription to the number of patients ratio, (v) the number of prescription to the number of prescribers ratio, (vi) the number of the maximum prescriptions per patient, and (vii) the number of the maximum prescriptions per prescriber. A dataset of 879 products with 7 characteristics for each product was constructed. According to the international literature the Local Correlation Integral (LOCI) algorithm [4] is one of the latest algorithms for outliers' detection giving more accurate results on several fields of study [5] compared to other algorithms. Based on this, LOCI was applied to detect any outliers on the dataset, setting the user selected parameter to default values, i.e. $\alpha=0.5$, Nearest Neighbors=20, and Threshold=3, producing some fruitful results. The results revealed that 7 out of 879 products could be characterized as outliers on this seven dimensional space. All of them had different behavior and space distribution, being further away from the rest of the data representing the other products. The 7 outliers may be assumed that have been associated with fraud, since at least two of them have been already confirmed as such by the EOPYY's Auditing Services and the rest are still under investigation.

3. Conclusions

According to the results of this study, the applied outlier detection approach can support and help the fraud detection process conducted by the auditing services in the Healthcare sector. Future work will include the application of multiple algorithms on the healthcare expenditures datasets to achieve more accurate results, while it will also be expanded to the detection of frauds on the prescribers' level.

Identification of EMCI in MR Brainstem Structure Using Fractal Measures and Random Forest Approach

Rohini PALANISAMY¹ and Ramakrishnan SWAMINATHAN

Department of Applied Mechanics, Indian Institute of Technology Madras, India.

Abstract. In this work, an attempt has been made to assess the texture variations of brainstem occurring in the Early Mild Cognitive Impairment (EMCI) condition. Fractal dimension is calculated for the segmented brainstem volume using Higuchi's and Detrending moving average (DMA) method. These measures are validated using Random forest classifier. DMA shows better performance when compared to Higuchi's method in categorising EMCI stage. Thus, the proposed approach using brainstem image's DMA fractal measures with random forest can be used in diagnosis of EMCI.

Keywords. Early Mild Cognitive Impairment, Brainstem, Higuchi's Fractal analysis, Detrended Moving Average, Random forest

1. Introduction

Early Mild Cognitive Impairment (EMCI) describes the clinically asymptomatic stage of Alzheimer's disease (AD). Research on neuropsychiatric symptoms presented by AD patients suggests the early changes in brainstem image texture. Fractals are proven to be effective measures to describe the texture changes in brain tissue.

2. Methodology

Raw T1-weighted age- and gender-matched MR images comprising of 232 EMCI, 200 normal and 200 AD subjects are considered from ADNI database. The images are preprocessed and brainstem volume is segmented using fuzzy based connected component technique. Fractal dimension (FD) is evaluated using Higuchi's method and Detrended Moving Average (DMA) technique. Higuchi's method estimates FD using gray values of pixels and their neighbors. DMA is the advancement of Higuchi's method where, the trend present in the image gray values are removed using root mean square function and the FD values are estimated on the detrended image volume. The extracted fractal measures are further validated using random forest in classifying EMCI stage.

3. Results and Discussion

Representative raw and processed images are shown in Figure 1. The raw images in Figure 1(a) are spatially registered, skull stripped and contrast enhanced as shown in Figure 1(b) and Figure 1(c) respectively. Brainstem volume in Figure 1(f) is segmented from the white matter tissue shown in Figure 1(d). Figure 2(a) shows the linear fit of double log plot calculated using Higuchi's algorithm. The variations in the fluctuation function for different scale obtained using DMA technique is shown in Figure 2(b). The

¹ Corresponding Author, E-mail: rohini2678@gmail.com

slope of double log plot is found to be different for normal, EMCI and AD condition, stating the variations in the fractal nature of brainstem structures. Figure 2(c) shows the box plot indicating mean and standard deviation of fractal values for EMCI, normal and AD subjects. It can be seen that the mean of fractal values calculated using DMA is well separated when compared to Higuchi's method and shows significant differences in distinguishing EMCI condition. As the fractal values are indirect measure of texture heterogeneity, it can be seen that the brainstem images of EMCI patients are comparatively less heterogeneous than normal and AD subjects. This may be due to changes in the neuronal structure during the preclinical stages of the disease. The changes in FD values are further validated using random forest classifier where, an accuracy of 89% is achieved using DMA in classifying the EMCI stage.

Figure 1. Representative images of (a) raw (b) spatial normalized (c) skull stripped (d) white matter tissue (e) segmented brainstem structure (f) 3D brainstem volume

Figure 2. Double logarithmic plot representing FD calculated using (a) Higuchi's and (b) DMA method (c) Box plot representing FD changes among EMCI, normal and AD

4. Conclusion

FD is able to capture the subtle changes in the fractal nature of the brainstem images. The variations in FD obtained using DMA for brainstem volume are found to be significant in differentiating EMCI condition. Brainstem image's fractal measure is found to be distinct in defining the clinical pathology and classifying the EMCI stage, and hence can be used for preclinical diagnosis of AD.

Identifying and Assessing Competencies for Staff Working in Public Health Emergencies

Heini UTUNEN^a, Andrew BLACK^a, Oliver STUCKE^a, Melissa ATTIAS^a, Gaya M GAMHEWAGE^a

^a *World Health Organization*

Abstract. Competency-based learning involves identifying the knowledge, skills and attributes required for carrying out workplace roles. In 2018, the World Health Organization's (WHO) Health Emergencies Programme (WHE) introduced a competency framework with competency-based assessment (CBA) methodology. The CBA focuses on behavioural indicators that participants demonstrate and training faculty observe during training events. This article introduces the CBA of WHE. It is essential to use the framework to design learning programmes and provide the basis to appraise and manage WHE personnel and team performance.

Keywords. Competencies, competency assessment, competency-based learning, learning and development, capacity building, health emergencies

1. Introduction

WHO has set a target of 1 billion more people better protected from health emergencies. To achieve that, a health workforce of excellence is needed, supported by a learning strategy that provides a framework for all learning using a competency-based approach.

Competency-based learning has been derived from Human Resources practices of identifying the knowledge, skills and attributes required for staff to complete the roles assigned to them and linking these roles to the goals of the organization [1]. Employers have made the distinction between core competencies that should be demonstrated by all employees and functional or technical competencies that are required for staff to perform specific roles [2]. In emergency work where staff and leaders face unique pressures, their ability to demonstrate the core competencies becomes particularly important [3]. WHE has followed this model in the roll-out of its competency framework.

2. Method

WHE core competencies are a subset of WHO competencies: Moving forward in a changing environment, applying technical expertise, communication, teamwork, building and promoting partnerships, and leadership. The competencies are demonstrated by 49 observable behaviours. WHE initiated CBA to determine how competencies are met by staff undergoing training and simulation exercises. Participants are assessed by observers and scored based on their demonstration of the behaviours. The scores are aggregated to indicate areas of strength and weakness for each participant and of the whole training cohort. Competency-based discussions are held between

participants and training faculty before and after a training event. These discussions are designed to help participants reflect on the behaviours they feel they readily demonstrate and those which they would like to develop through further learning.

3. Results

The CBA has been piloted in four training activities with approximately 100 participants. It was found that where participants were observed against all 49 behaviours throughout the entire training period, the assessment provided an indication of strengths and areas for development which were largely in line with the participants' self-assessments. Where the number of behaviours observed was reduced, the assessment provided less indication and was less helpful in guiding out-brief conversations with participants. A greater number of facilitators conducting observations improved the assessment consistency. It was also found that it was necessary to conduct a face-to-face training and briefing for the competency observers. Scores for all participants of a training activity are also aggregated into a gross finding to give an indication of areas of strength and weakness for the entire cohort. These can be addressed in future learning programmes.

4. Discussion

The CBA has provided invaluable input in producing meaningful feedback for learners about their demonstration of core competencies. It is also critical for the training owners to mark how the learning objectives are met and the need for further learning. WHE currently has core competencies that are essential for anyone working for WHO in emergencies. Functional competencies are encouraged to be developed by technical teams in charge of functional areas.

5. Conclusions

Providing objective and constructive feedback on behaviours can help an individual identify and reflect on his/her strengths and areas for development, which is a key part of the learning process. Competencies must be understood by the staff and personnel supporting a learning programme; faculty should be trained in their use for designing, delivering and assessing learning and training activities.

Abstract. The aim of this paper is to propose an approach based on preference learning for building a model that represents the closest possible experts reasoning to provide recommendations. We apply this method to antibiotherapy in primary care. The preference model was learned from the recommendations and from a database describing the domain.

Keywords. Preferences learning, Experts reasoning, Clinical Practice Guidelines

1. Introduction

Clinical practice guidelines (CPGs) are textual documents written by a group of experts. They contain recommendations and their justifications. In the domain of antibiotic prescription, we analyzed these justifications and showed that experts used antibiotic properties to recommend antibiotics [1,2]. The preference model used by experts is based on these properties, but still need to be explicitated, before to be implemented in a clinical decision support system (CDSS). Here, we propose a method for learning preferences [3,4] of CPG experts from both recommendations and a database containing the antibiotics and their properties. We aim at building a model that represents the closest experts reasoning to provide recommendations in the domain of antibiotherapy in primary care.

2. Methods

We used a database containing the antibiotics, their properties, and their rank of recommendations as defined in CPGs. This database was validated by antibiotic experts according to a Delphi process [1]. Let P be the set of properties of antibiotics of the database D . For each property $p_i \in P$, we denote the domaine of p_i by $dom(p_i) = \{1= True, 0=False\}$. Each instance d in D has a recommendation rank. Antibiotics having $R_d=1$ are preferred to those having $R_d=2$ which are also preferred to those having $R_d=3$ which are also pre-

¹Corresponding Author: Karima Sedki, E-mail: karima.sedki@univ-paris13.

ferred to those having $R_d=4$. Antibiotics having R_0 are not preferred since that are not recommended. The aim is to learn preference rules from antibiotics properties, which will allow to associate the same recommendation ranks that those defined in CPGs. Let us give in the following definitions.

Definition 1 (Item) *Each element that is built on the connective logic \wedge and contains at most two properties $p_i \in P$ is called an item. The set of items is denoted by I . We define $Sat(d \in D, x \in X)$ a function that returns True if instance d satisfies item x .*

Definition 2 (Preference rule) *A preference rule r is a partial order in the form of $x_1 \succ x_2 \succ x_3 \succ x_4$ where x_i is an item defined in Definition 1.*

The aim is to define the best items. Hence, we define in the following the support of each item regarding each recommendation rank.

Definition 3 (Support) *The support of an item $x \in X$ regarding instances $d \in D$ having a recommendation rank $R_d = r$ is defined as:*

$$Supp(x, r) = \frac{|\{d \mid Sat(d, x) \text{ and } R_d = r\}|}{|\{d \mid R_d = r\}|}$$

Computing the support of each item regarding each rank allows to determine which item is best for that rank. The interest of an item increases with its support. Our method is summarized as follows:

1. Generate the list of possible items I following Definition 1.
2. Compute the support of each one regarding each recommendation rank R .
3. Determine best items ($BestR_i$) for each R . They are those having the support superior than the fixed minimal support ($thresholdSupp$ is in the $]0, 1]$). Different preference formulas can be generated.

3. Conclusion

The aim of this paper is to propose an approach based on preference learning for building a model that represents the closest possible experts reasoning and strategies to provide recommendations. In the future, we aim at validating our approach in other infectious diseases, and then implementing the preferences rules in AntibioHelp® a CDSS for antibiotic prescription in primary care.

Identifying Indicators to Assess and Monitor Data Integration Engines Systems

Priscila MARANHÃO^a, Ana Margarida PEREIRA^a, Ricardo J. CRUZ-CORREIA^{a,b}

^a*Center for Health and Technology and Services Research - CINTESIS, University of Porto, Portugal*

^b*HealthySystems, Portugal*

Abstract. We aimed to identify relevant indicators for end-users in integration engines for healthcare systems. Methods: The study was performed in two steps, including interviews and the identification of additional indicators from the literature. Results: 10 interviews were performed and 90 indicators identified. Discussion: Several of the indicators are difficult to calculate, nevertheless, they have the potential to improve data quality and processes in healthcare institutions and should be further explored in future studies.

Keywords. Integration, indicators, interoperability

1. Introduction

Integration engines are critical in the transmission of clinical and demographic data, maintaining accessibility and integrity within healthcare institutions worldwide [1]. Indicators to assess and monitor data integration engines are essential, contributing both to improve data quality and to facilitate systems management [2]. This study aims to identify relevant performance indicators for end-users regarding the implementation of integration engines.

2. Methods

Data were collected using a 2-step exploratory qualitative approach. The first step was an individual interview with expert professionals from health institutions/health companies that used health information systems daily/almost daily. They were asked to identify indicators within four pre-selected relevant classes of indicators (identified by the authors based on literature review and personal expertise): Information System integration, Data quality, Performance, and Safety and General Data Protection Regulation (GDPR). Two new categories were identified during the interviews: Integration Management and Hospital workflow process. The second step was the identification of additional indicators from the literature [3,4].

3. Results

We performed 10 interviews and identified 63 indicators. Additional indicators (n=27) were identified in the reports. Table 1 presents a sample of the identified indicators by domain. A list of all indicators (n=90) is available at <http://shorturl.at/sIV28>.

Table 1. Indicators concerning integrated software systems per domain; only a sample is presented.

Information System integration	• Absolute n of messages delivered / n sent	• Calculate n of alerts by period of time
Data quality	• Data availability	• Total messaging problems
Performance	• Delivery/receiving time	• N of SLA metrics for integration
Safety and GDPR	• Access history checking	• Key expiration time
Integration Management	• N of integration problems	• N of hours to set up/manage
Hospital work process indicators	• Number of coding errors	• Process reengineering

N – number; SLA – Service Level Agreement; GDPR – General Data Protection Regulation

4. Discussion

We believe that this study describes a relevant list of indicators that should be assessed and promoted within an integrated health system. Although several of the indicators are difficult to compute, they might contribute to improve data quality and processes in healthcare institutions, by promoting the identification and facilitating the correction of system inefficiencies or malfunctions, and should be further explored in future studies.

5. Conclusion

This study identified 90 indicators that can be analyzed by actors involved in the healthcare system and have the potential to contribute to data quality improvement.

Abstract. Seizure is a common complication in a neurological intensive care unit (NICU) and it requires continuous electroencephalograms (EEG) monitoring. Implementation of EEG for each bed in a NICU is very expensive and require labor work for interpretation of EEG. To provide an affordable device of EEG in NICU, we developed a low-cost wireless biosensor, which utilized the current standard of the internet of things technology (IoT). In this study, we implement a wireless biosensor for continuous EEG monitoring in NICU and discuss its feasibility. To provide a low-cost EEG device, we embraced Bluetooth and mobile phone technology, which is convenient for implementation. We build a two-channel EEG biosensor, which utilizes Bluetooth to transmit the signal to mobile phones. Then, mobile phones use Wi-Fi technology to send data to the server. Additionally, we also developed a registry to organize the patient's EEG data. In six months research period, we have 65.8% of patients collected successfully. Using 2 channel-biosensor in NCU is feasible. It also develops a neuromedical database by collecting and monitoring physiological signals to develop future neuromedical research.

Keywords. Continuous EEG, two-channel biosensor, Neurointensive care unit, wearable device

1. Introduction

Seizure is a common complication in a neurological intensive care unit (NICU), which the incident rate ranges from 3%-45% [1] and it requires continuous electroencephalograms (EEG)[2] monitoring. Implementation of EEG for each bed in a NICU is very expensive and require labor work for interpretation of EEG. To provide an affordable device of EEG in NICU, we developed a low-cost wireless biosensor[3-4], which utilized the current standard of the internet of things technology (IoT). In this study, we implement a wireless biosensor for continuous EEG monitoring in NICU and discuss its feasibility.

¹Corresponding author: E-mail: arbiterski@gmail.com

2. Method

To provide a low-cost EEG device, we embraced Bluetooth and mobile phone technology, which is convenient for implementation. We build a two-channel EEG biosensor, which utilizes Bluetooth to transmit the signal to mobile phones. Then, mobile phones use Wi-Fi technology to send data to the server. Additionally, we also developed a registry to organize the patient's EEG data.

3. Result

From April 1, 2019 to September 30, 2019, there were 369 patients and 42 patients excluded. After deducting repeat patients, the number of cases was 241. The age ranged from 16 to 96 years. The main diagnoses included intracranial hemorrhage (43.9%), infarction(24.1%), subdural hemorrhage (15.1%), subarachnoid hemorrhage (14.0%), brain tumor (9.2%), aneurysm (8.6%), seizure(6.2%) and epidural hemorrhage (4.3%). The male to female ratio was 58.3%:41.7%. We reviewed the EEG data in the database and then compared them with nursing records and found that they were consistent with the seizure attack time.

4. Discussion:

In six months research period, we collected 65.8% of NICU patients successfully. Those patients which cannot be collected were due to 1.Network connection (16.2%) 2.Patient skin irritation (11.9%), 3.Irritable patients (8.1%), 4.Wireless signal(6.5%), 5.Operation wound (3.2%), 6.Out of battery (1.2%). To improve the above issues, we need to design a better server program that can stably pass data. For the skin irritation, we try to use some field for skin protection. Irritable patients will be excluded until the condition is stable. To enhance the wireless signal, the Bluetooth connective firmware needs upgrades and the mobile phone can be closer to the biosensor. The operation wound some times would overlapping on where we stick the sensor lead. To prevent influenced the treatment and infection, we exclude these cases. The battery wears in NICU stronger another place because vapor inhalation treatment is often in NICU. During the study period, 7 of the 34 battery circuit boards became rusty. Therefore, the development of a waterproof function is an essential topic in the future.

5. Conclusion

We can use wireless biosensor to collect continuous EEG and there were 65.8% of NICU patients collected successfully. It also develops a database by collecting and monitoring physiological signals to develop future neuromedical research.

Implications of Clinicians' Attitudes Towards Clinical Decision Support Systems

Anshu ANKOLEKAR^{a,1}, Britt VAN DER HEIJDEN^a, Andre DEKKER^a, Cheryl ROUMEN^a, Dirk DE RUYSSCHER^a, Bart REYMEN^a, Ruud HOUBEN^a, Peter FICK^a, Sander PUTS^a, Joeri VEUGEN^a, Adriana BERLANGA^b, Cary OBERIJE^c, Rianne FIJTEN^a

^c The D-Lab, GROW - School for Oncology and Developmental Biology, Maastricht University Medical Centre+, Maastricht, The Netherlands

Keywords. Shared decision making, decision aids, clinical decision support, lung cancer

1. Introduction

Clinical decision support systems (CDSSs) can provide personalized predictions for cancer patients, such as overall survival and risk of side-effects associated with different treatments. Combined with shared decision-making (SDM), CDSSs can guide treatment decisions by supporting data-driven decision-making in line with patient values. Prior findings have established the value of SDM and CDSSs in improving care, yet implementation remains a significant hurdle due to barriers such as lack of accessibility, lack of clarity about the tool's purpose, time pressure, and poor design.

The purpose of this study was to explore the potential for implementing a CDSS in combination with SDM in the lung cancer trajectory in the Netherlands from the perspective of lung cancer specialists.

2. Methods

We used a mixed methods design consisting of qualitative interviews with 9 Dutch lung cancer specialists (7 pulmonologists and 2 radiation oncologists) and a retrospective cohort study on MTB treatment decisions of 257 non-small cell lung cancer (NSCLC) stages I-III patients in our clinic. Interview themes included the treatment decision-making process, clinician views on CDSS and their requirements.

¹ Corresponding Author, Department of Radiation Oncology (MAASTRO Clinic), GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre+, Maastricht, The Netherlands; E-mail: anshu.ankolekar@maastro.nl.

In addition, we determined the percentage of lung cancer patients that deviate from MTB recommendations and their reasons for deviation. We also compared the treatment outcomes and quality of life of deviating patients with those of non-deviating patients with chi-square and t-tests respectively.

3. Results

The majority (78%) of the clinicians were receptive towards CDSSs overall but cited barriers such as lack of trust in current prediction models, lack of validation studies, and time pressure. They felt a CDSS would be most valuable during the MTB discussion between clinicians rather than in consultations with patients. Current MTB recommendations are based on clinician experience, clinical guidelines and patients' WHO performance status, and our cohort study revealed that in 89% of cases these recommendations were followed by patients. Indeed, although the specialists were supportive of SDM initiatives, the majority felt that it is difficult to practice in lung cancer as there is often one 'best' treatment option.

Of the patients who deviated from MTB recommendations, 82.1% did so in order to choose a less intensive treatment. We found no significant differences in overall survival and toxicity between the two patient groups and a minor increase in quality of life in the deviating group.

4. Discussion

Our findings have implications for developing and implementing CDSS and SDM in lung cancer treatment. First, MTBs are generally characterized by lack of time, failure to reach decisions, and failure to take patient preferences into account. Second, clinicians' survival predictions are positively biased and radiation oncologists are limited in their ability to predict lung cancer treatment side effects. This contrasts strongly with our finding that clinician experience was the primary factor influencing MTB decisions, and underlines the need for data-driven CDSS.

Furthermore, when clinicians are skeptical of CDSSs due to lack of validation studies, steps can be taken to involve them in a user-centered design process so that their inputs, requirements, and feedback guide CDSS development. Finally, integrating the CDSS into the existing workflow is crucial to minimize the additional time required for clinicians to fill in patient data.

5. Conclusion

There is scope for CDSSs to support decision-making in lung cancer treatment, however care must be taken to incorporate these CDSSs into the clinical workflow.

Incorporating Tacit Knowledge of Experts in the Assessment of Shelters Under Disaster

Masaharu NAKAYAMA, MD, PhD ^{a,1} and Tadashi ISHII, MD, PhD ^b

^aMedical Informatics, Tohoku University Graduate School of Medicine, Miyagi, Japan.

^bDepartment of Education and Support for Community Medicine, Tohoku University Hospital, Miyagi, Japan

Abstract. During disasters, prompt assessment of evacuation centres and appropriate measures taken based on the assessment are important for protecting local residents' lives and health. To clarify experts' tacit knowledge for improving the management of shelters under disaster, we conducted a questionnaire survey of specialists in disaster management to examine the assessment items to which they accorded top priority. Our results suggest that specialists give highest priority to the number of evacuees, followed by infrastructure and need for medical intervention. Identifying their common views on priorities can be the first step towards taking standard appropriate measures in evacuation centres.

Keywords. disaster management, shelter, Great East Japan Earthquake

1. Introduction

The Great East Japan Earthquake (GEJE) and tsunami on March 11, 2011, caused an unprecedented disaster with 15,897 deaths and 2,534 missing persons as of December 10, 2018 [1]. During the disaster, many people (around 400,000) were evacuated to temporary shelters, such as schools, gymnastic halls, and public halls in Northeast Japan. Several organized teams cooperating with disaster specialists, various medical institutions, and local government officials managed to improve the conditions of the shelters [2]. It is important to understand how disaster experts make a decision based on the status of a shelter, which would be useful for all potential managers in future disasters. Our study aimed to clarify the algorithm through a questionnaire survey.

2. Methods

We conducted a questionnaire survey on 11 disaster management experts who had experienced the GEJE in 2011 or the Kumamoto earthquake in 2016. The research protocol was approved by the Tohoku University Graduate School of Medicine Research

¹ Corresponding author: 1-1 Seiryomachi, Aoba-Ku, Sendai, Miyagi 980-8574, Japan;
E-mail: nakayama@cardio.med.tohoku.ac.jp

Ethics Committee. The questionnaire comprised two questions, to examine 1) which of the 30 assessment items is given top priority and 2) whether a facility accommodating 100 people (a larger shelter) with medium urgency or a facility accommodating 10 people (a small shelter) with greater urgency should be given priority, for each assessment item. More respondents favoured the former. Opinions were divided on the importance of the number of diseased/injured people.

3. Results

The number of evacuees received the highest priority, followed by drinking water supply, information about diseased or injured people, basic information, number of diseased or injured people, electricity, sanitation, and information about people who require assistance. Next, to examine whether the priority changes depending on the number of evacuees and severity, we asked respondents to consider which they would give priority to between a shelter accommodating 100 evacuees (a larger shelter) with medium urgency and a shelter accommodating 10 people (a small shelter) with greater urgency for each assessment item. Most of them felt that the larger shelter required priority even though the smaller shelter was in a more serious situation. Among the 30 items, electricity, waterworks, drinking water supply, and food supply were evaluated as relatively important.

4. Discussion

Our results suggest that specialists give highest priority to the number of evacuees, followed by infrastructure and need for medical intervention. Clarifying specialists' common views on priorities is the first step in identifying standard appropriate measures in evacuation centres. The present study has several strengths. First, our results suggest that specialists give highest priority to infrastructure and need for medical intervention. The study presents the tacit knowledge of specialists who are considerably experienced in disaster management. Second, this study also revealed a slightly different priority based on urgency. This implies that information to evaluate the urgency of shelters is crucial at the headquarters when an area is struck by disaster, resulting in shelters needing support using limited resources of manpower, medicines, food, and water. As advance preparation to establish an initial response system and decision-making is critical for disaster response management, this study's findings may be useful in doing so.

Integrating Socially Assistive Robots into Japanese Nursing Care

Markus KOLSTAD ^{a,1}, Natsu YAMAGUCHI ^b, Ankica BABIC ^{a,c} and
Yoko NISHIHARA ^d

^a*Department of Information Science and Media Studies, University of Bergen, Norway*

^b*College of Law, Ritsumeikan University, Japan*

^c*Department of Biomedical Engineering, Linköping University, Sweden*

^d*College of Information Science and Engineering, Ritsumeikan University, Japan*

Abstract. This paper presents experiences of integrating assistive robots in Japanese nursing care through semi-structured interviews and site observations at three nursing homes in Japan during the spring of 2019. The study looked at experiences with the robots *Paro*, *Pepper*, and *Qoobo*. The goal was to investigate and evaluate the current state of using robots in the nursing care context, firsthand experiences with intended and real use, as well as response from the elderly and nursing staff. The qualitative analysis results pointed out user satisfaction, adjusted purpose, therapeutic and entertaining effects. Potentials of robots to assist in elderly care is advantageous. Limitations currently relate to the lack of ways to fully utilized and integrate robots.

Keywords. Assistive Robots, Nursing Care, Human-Robot Interaction (HRI), Therapy, Communication, Impact on Care.

1. Introduction

According to the United Nations (UN) demographic statistics, Japan's population has decreased since 2009. Japan's population today (2019) is about 126,800,000, but the forecast is that the number will fall to 108,800,000 by 2050 [1]. Moreover, Japan currently holds the world's largest population of elderly per capita with about 27% of Japan's population being 65 years or older. In order to cope with the changing demographic, possible solutions are to decrease the need for more human workers through innovation and to keep the elderly as independent as possible for longer.

The Japanese government has presented six priority areas where robot technology is to be introduced in nursing care, one of them being *monitoring and communication systems* [2]. We visited three different Japanese nursing facilities in order to see how robots are being used, what impact they made on the nursing care, and what positive and negative experiences the elderly and staff could share. The interviews focused on communication robots, being one of the newest items introduced as the government's priority areas whose development has been supported since 2017.

¹ Kolstad Markus, Department of Information Science and Media Studies, University of Bergen, Norway;
E-mail: markuskolstad@gmail.com.

2. Methods

The three nursing facilities were chosen as the study sites from a public list of nursing facilities using the robot *Paro* [3]. The interviews were not limited to *Paro* exclusively, but rather aimed at acquiring information on all interactive robots used at each facility (*Paro* was used at all 3 facilities, *Pepper* at two, and *Qoobo* at one). The interviews were primarily held with the facilities' managers and nursing staff in addition to observations of patients interacting with robots. The interviews were analyzed using open coding.

3. Results

The interviews suggested that these kinds of robots all work with the mind and the mental wellbeing of the patients. Patients suffering with dementia often believe *Paro* to be a dog or even a human baby, treating and interacting with it accordingly. Patients often cared and worried for *Paro*, thus indicating an emotional relationship. Interacting with *Paro* evoked memories about their childhood dog or child nursing days. *Paro* was found effective on both male and female patients if they liked animals, but patients that are more cognitively capable might find *Paro* less interesting. The use of robots has also depended on the nursing staff attitude. *Pepper* is used for recreation, entertaining patients through games and karaoke. Still, some patients found it loud and annoying. *Qoobo* was mostly used by one patient not interested in people but happy with the robot.

Discussion

Robots can be superior to the use of dolls or animals as therapeutic aids should be safe and have demonstratable therapeutic effects. Robots like *Paro* can work as an alternative to pet/animal therapy without the risk of allergy, bites, scratches, unpredictability, infections or even stress for the animal itself. However, some people dislike certain animals which makes them skeptical to animal-type robots as well. *Pepper* is mostly used to entertain, in addition to Taiso, the daily Japanese stretching exercise. However, the need for human workers is not eliminated. Ultimately, these robots are used to assist and relieve the humans from work overload. Patients, that usually did not smile to the human staff, were seen smiling and talking to the robots. Additional positive effects were increased interest of groups and often grandchildren to visit the nursing homes.

Conclusion

Positive effects were patient satisfaction, joy, and mood changes. On the downside, robots are not fully independent and demand staff attention which limits their use.

Abstract. The healthcare environment in Serbia has changed dramatically over a last two decades, pointing out the necessity of clinical informatics (CI) education for future MDs. Total of 77 students were enrolled and 72 (93.5%) have successfully finished this course during 4 academic years. Mean total score for all students was 83.4 ± 9.0 points, without difference between genders. We presented blended learning module as an effective way of gaining competences in CI and recommend this course to be required for future MDs.

Keywords. clinical informatics, education, blended learning

1. Introduction

The healthcare environment in Serbia has changed dramatically over the last two decades, pointing out the necessity of clinical informatics (CI) education for future MDs [1]. Therefore, our main goal for development and implementation of clinical informatics course was to enable students to better understand the uncertainty of medical data, information and knowledge via blended learning mode as effective strategy in delivering education [2,3].

2. Method

Clinical informatics was first introduced in 2015/16 as an elective course for 6th year medical students of Medical Faculty University of Belgrade. This elective course was among 20 proposed, and a minimal number of students had to preselect it in order to be enrolled. Curriculum was developed to enable students, future MDs, to understand the uncertainty of medical data, information and knowledge. Course

materials included four topics and two projects (Figure 1). The blended teaching approach combined on-site lectures and interactive multimedia didactic materials which were accessed through the Moodle Learning Management System (LMS). Course competences were evaluated through projects, quizzes and knowledge test with maximum total score of 100.

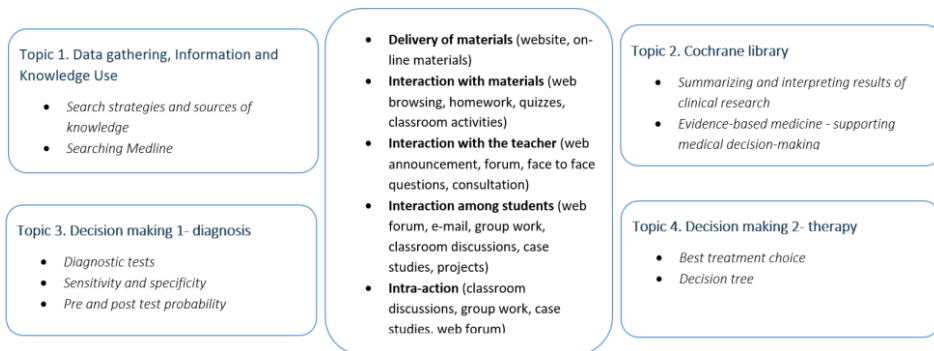

Figure 1. Structure of Clinical informatics Course

3. Results

During the past four academic years, 77 medical students chose Clinical informatics as an elective subject. Seventy-two (93.5%) successfully finished the course. Competences assessment, presented by mean total course score of 83.4 ± 9.0 (for all enrolled students), suggested that students adopted knowledge and skills necessary for medical decision making in conditions of uncertainty. There were no gender differences, as well as no significant changes in scores over a 4-year period.

4. Conclusion

Clinical informatics course is an effective way for medical students to gain competences needed to better understand the medical data uncertainty. In the era of an overwhelming presence of new technologies supporting both learning and health care delivery, clinical informatics should become an obligatory course in medical school curricula.

Abstract. Extracting patient phenotypes from routinely collected health data (such as Electronic Health Records) requires translating clinically-sound phenotype definitions into queries/computations executable on the underlying data sources by clinical researchers. This requires significant knowledge and skills to deal with heterogeneous and often *imperfect* data. Translations are time-consuming, error-prone and, most importantly, hard to share and reproduce across different settings. This paper proposes a knowledge driven framework that (1) decouples the specification of phenotype semantics from underlying data sources; (2) can automatically populate and conduct phenotype computations on heterogeneous data spaces. We report preliminary results of deploying this framework on five Scottish health datasets.

Keywords. health data, phenotype computation, data integration, ontology

1. Introduction

Health data in the UK is stored in different local communities, meaning they are maintained locally and stored in inconsistent formats and languages. A key technical challenge haunting almost all clinical studies is to extract or compute accurate patients' phenotypes (traits of symptoms, diseases, medications or biochemistry test results) from such a fragmented data space. Specifying the computations of a phenotype requires (each time) significant human effort to understand database details, good data science skills to do the querying and data manipulating, and caution & patience to deal with data incompleteness/inconsistencies. Such phenotype specifications can hardly be reused as the consequence of the heterogeneous data models across jurisdictions. This significantly impedes the reusability and reproducibility of clinical researches.

2. Method

The main aim of this study is to realise a clinical data science framework [1] that makes the underlying data sources *transparent* to phenotype computations. The key is to decouple the formalisation of phenotype semantics and the technical details of underlying data sources. We propose an architecture to implement such a decoupling, which is composed of the following two aspects.

¹Corresponding Author: 9 Little France Road, Edinburgh EH16 4UX, UK; E-mail: honghan.wu@ed.ac.uk.

Phenotype Formalisation Framework This has three components: (1) A database independent phenotype formalisation using Semantic Web knowledge representation technologies to define phenotype semantics; (2) A core phenotype ontology serving as the base vocabulary linking to standard clinical terminologies available at BioPortal (e.g., SNOMED CT, ICD10); (3) A query formatter that generates ontology queries from an user interface. The formatter can automatically translate phenotype definitions between standard terminologies (e.g., READ to SNOMED CT).

Ontology Based & Rule Driven Data Access To automatically compute the above formalised phenotypes on actual data, we adopt ontology based data access (OBDA) techniques [2] but with a novel extension to support rules. Such an extension is necessary because the semantics of most phenotypes are not fixed. They either change with research focuses or different researchers might have different opinions about certain rules related to a phenotype. For this reason, in our framework, we minimise the ontology. Instead, a **rule engine** is implemented to allow flexible definitions of phenotypes. The engine can automatically convert user specified rules into new data mappings, which will be translated on the fly to do phenotype computations on databases.

3. Deployment and Evaluation

This study was supported by Health Data Research UK (<https://www.hdruk.ac.uk/projects/graph-based-data-federation-for-healthcare-data-science/>) and the Medical Research Council [grant number MC_PC_18029] as an exemplar to create a federation of distributed health data in Scotland. The above described framework has been deployed on 5 synthetic data sets generated using BadMedicine [3], which represents data/schema characteristics learnt from real data. Due to space limitations, we put the full benchmark and evaluation details on a Github page: <https://github.com/Honghan/KGPhenotyping/tree/master/evaluation>.

4. Conclusion

To overcome *obscure* phenotype computation, which makes experiments difficult to understand and reproduce, we developed a new framework to allow clinical researchers to formalise phenotype semantics independently to the data and, more importantly, in a computer understandable way so that its computation can be automated on the underlying data sources. We implemented a knowledge-driven (based on ontologies and rule languages) approach to define an interlingua in which practitioners can represent the phenotype semantics they want to use and automatically translates this to computations as database queries on participating data sources.

Abstract. Several drug databases exist, but sometimes differ in their content. Here, we propose a taxonomy of the variability we observed, and we present a tool for investigating the variability through the visual comparison of the properties of a given drug as represented in several sources or databases.

Keywords. Drug databases, Computer Graphics, Nonverbal Communication

1. Introduction

It is known that drug databases suffer from many discrepancies, both intra- and inter-databases. In a recent project named VIIIP (Integrated Visualization of Information on Pharmaceutical Innovation) [2], we aimed at comparing new drugs to the older ones with the same indication, on the basis of their properties. We planned to extract these properties from drug databases. However, we encountered many problems related to the quality and the structure of these databases, which impaired the project.

2. Methods

We compared the 4 drug database available in France, a Natural Language Processing (NLP) tool [3], and a manual coding by an expert pharmacist (HB), for 10 drug. We used ICD10 and MedDRA terminologies. We analyzed the differences between sources and built a taxonomy of variability. We also used rainbow boxes, a set visualization technique [1] that was initially designed for comparing similar drugs [2]. We adapted it for comparing the properties of the same drug, described by 6 sources.

3. Results and discussion

We identified 3 main causes of variability in drug knowledge:

1) Differences in the writing of SPCs: when two drugs share a common property, it might be described differently in their SPCs. It includes: 1a) Variability in the

presentation of the SPC, e.g. plain text and/or table; 1b) Variability in the file format, e.g. PDF vs HTML; 1c) Variability in the wording; 1d) Variability in the level of granularity (e.g. “liver injury” vs a list of 10 conditions that are the 10 most common liver injuries).

2) Differences in the drug databases: each database has its own structure and editorial practice. It includes: 2a) Missing information (e.g. seriousness of adverse effects); 2b) Structural limitation, when the desired information is present but not structured or coded (e.g. information available in free text only); 2c) Poor information quality; 2d) Heterogeneous coding, when the same information is coded differently for various drugs.

3) Each drug database employs several experts, having their own coding practice.

Figure 1 shows the variability found at level #2. Sources are shown in columns and ordered by similarity. Rectangular boxes indicate the adverse effects. Boxes that span over several columns represent adverse effects present in several sources. Box colors indicate the frequency of the adverse effects, from rare (yellow) to frequent (orange).

In conclusion, it appears that drug databases are designed for providing information on a single drug, but not for comparing two or more drugs.

Funding: This work was partly supported by the French drug agency (ANSM) through the VIIIP project (AAP-2012-013).

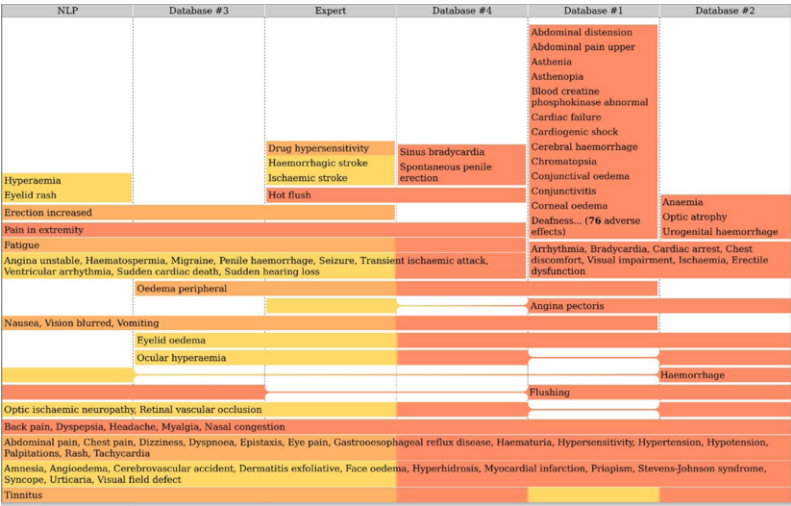

Figure 1. Rainbow boxes comparing the adverse effects of Cialis® from 6 sources.

Linking Genome and Exposome: Computational Analysis of Human Variation in Chemical-Target Interactions

Liana BRUGGEMANN^a, Christopher HAWTHORNE^b, Ram SAMUDRALA^a and Guillermo H. LOPEZ-CAMPOS^{b,1}

^a*Department of Biomedical Informatics, State University of New York (SUNY), Buffalo, NY, USA*

^b*Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, UK*

Abstract. The growing amount of available public data repositories containing a plethora of rich chemical and biomedical information is enabling new in silico research avenues. In this project we aim to link human genome variations and the exposome applying in silico biomedical informatics approaches to analyse the potential effects of those variants in the interactions with different chemicals.

Keywords. Translational bioinformatics, Protein modelling, exposome, single nucleotide variant, toxicogenomics.

1. Introduction

Nowadays, human societies are living in an environment where individuals are exposed to an increasing number of xenobiotic chemicals. The acknowledgment of the importance of these and other exposures led to the development of the concept of the exposome defined as the whole set of exposures of an individual (including, chemical, biological, physical or and social exposures) [1]. The exposome could affect the human phenotype along with the genome and therefore its understanding could be important in the development of precision medicine.

Two decades ago, toxicogenomics was developed combining toxicology with genomics and post-genomics approaches to study the effects of the exposures to chemicals and chemical toxicants. Biomedical informatics has played a key role in this discipline, providing tools and methods to analyse, store and integrate the results from these “omics” techniques. More recently, the development of modelling and simulation tools and methods designed to predict the potential interactions of newly designed chemicals with biological targets (mostly hormone and other cellular receptors) has been another important area of development. Toxicogenomics can be considered as the toxicological relative of pharmacogenomics. An important area of research in the latter is the analysis of the effects of the genetic variants in the response to different drugs, and this has led to different applications and biomedical informatics resources. The analysis

¹ Corresponding Author, Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, 97 Lisburn road, Belfast, BT9 7BL, United Kingdom; E-mail: g.lopezcampos@qub.ac.uk.

of individual genetic variation is an aspect that has not been explored in detail in the area of toxicogenomics. Therefore, in this work we propose the development of a computational analytical pipeline designed to integrate the increasing amounts of information related with human genetic variation and the chemical component of the exposome analyzing the effects of different coding variants in the interactions with chemical compounds.

2. Methods and Results

As a proof of concept for our approach we have chosen to analyse the effects of the different coding genetic variants in the human Estrogen Receptor 1 (ESR1) and how those would affect the interactions with bisphenol-A (BPA), a chemical compound known to link with ESR1 and a potential endocrine disruptor due to its actions as a xeno-estrogen.

For the analyses we selected the wild type (WT) sequence and five single nucleotide variants (SNV) (R269C, R269H, M315V, E330K and R477Q) in the ESR1 gene. These variants were chosen as they were condign variants, they were not known to be pathogenic, were not located in the catalytic/binding site of the protein and had some of the higher minor allele frequencies for the variants in this gene.

We first used I-Tasser [2] to predict the ESR1 structure beyond the resolved region available and then we modelled our five variants using SCWRL [3]. Finally, we used those models to simulate the protein/ligand docking and calculate the binding affinities for BPA and estradiol for each of the five mutants and the wild type structures using CANDOCK [4]. As expected the results showed (table 1) that there was a higher affinity in this case for the natural ligand (estradiol) than for the xenobiotic (BPA) as well as that the effect in the reduction of the binding activity was more intense for the natural ligand than for BPA in all the analysed variants.

Table 1. Table showing the binding affinities (Kcal) for the wild type and the five variants analysed.

	Wild type	R269C	R269H	M315V	E330K	R477Q
Estradiol	-64.2911	-48.8941	-48.8198	-46.3230	-50.8965	-47.6796
BPA	-47.4722	-36.5059	-39.6272	-41.1594	-39.5739	-41.2424

With this approach we brought together genomics and exposomics applying in silico approaches. This strategy can be extended for the analyses of other targets and variants for the different chemicals to which individuals are exposed daily

Lower Respiratory Tract Infections in Children, Weather and Google Search Trends

Manuel RODRÍGUEZ TABLADO^a, Paula GONZALEZ PANNIA^a, Fernando C. FERRERO^a, Santiago ESTEBAN^a

^a*Health Ministry, Ciudad Autónoma de Buenos Aires, Argentina.*

Abstract. This is an exploratory study on different variables known to be associated with epidemiological outbreaks of lower respiratory tract infections in children under 2 years raised to identify patterns and potential predictors for making strategic decisions in terms of strengthening health teams in periods of greatest demand.

Keywords. Electronic Health Record, lower respiratory tract infection, weather, Google search.

1. Introduction

Lower respiratory tract infections (LRTI) are one of the most frequent causes of medical consultation, hospital admission and mortality in children with a very marked seasonal incidence [1]. These characteristics determine healthcare systems to be overloaded at the times of the year with higher demand for this group of pathologies.

This is an exploratory study on different variables known to be associated with epidemiological outbreaks of LRTI in children under 2 years [2], [3] raised to identify patterns and potential predictors for making strategic decisions in terms of strengthening health teams in periods of greatest demand.

2. Methodology

We analyzed the proportion of LRTI consultations and hospital admissions for all causes in patients under 2 years, climatological variables (air temperature, humidity and atmospheric pressure) and Google search trends on respiratory symptoms keywords. Data of consultations were extracted from the EHR of the public health system of the City of Buenos Aires. Consultations related to LRTI were detected using a rule-based algorithm validated using as gold standard the manual review of the medical records (precision 85.96%, recall 82.35%, F1 score 84.12%). Hospital admissions data were extracted from an administrative database of all the hospitals of the public health network of the City of Buenos Aires and we included admissions for all causes due to many missing data about the cause of admission (35.5% of missing data). The information related to Google searches included the terms "cough", "bronchiolitis" and "flu" in Spanish (pediatrician experts selected them as main terms used by parents as cause of consultation) and the average relative popularity of these terms was calculated. We

analyzed weekly averages or accumulated totals since 2017-01-01 to 09-30-2019 to assess seasonal trends and the relationships between them.

3. Results

We found a very strong relationship between air temperature (Spearman's rank correlation coefficient -0.89 , $p < 0.001$) and Google search trends (ρ 0.89 , $p < 0.001$) with the proportion of medical consultations for LRTI (**figure 1**). It is interesting that the LRTI consultation curve rises rapidly in the first weeks in which the temperature begins to fall. Google searches do not seem to have a pattern that allows for predictive analysis. Weaker relationship was found with hospital admissions (ρ 0.44 , $p < 0.001$), atmospheric pressure (ρ 0.62 , $p < 0.001$) and humidity (ρ 0.40 , $p < 0.001$).

Figure 1. Relationship between air temperature and Google search trends with the proportion of medical consultations for LRTI.

4. Conclusions

This is a novel study about climatological variables and clinical information using the EHR in the City of Buenos Aires. Further investigation should be made in order to make informed decisions regarding strategies to strengthen the health care systems in times of greatest demand. Air temperature seems to be the most important factor that could predict new outbreaks of LRTI.

^cLITIS EA4108, Rouen University, France

^dAssistance Publique-Hôpitaux de Paris, DRCI, Paris, France

Abstract. A lexical method was used to map ICD-11 to the terminologies included in the HeTOP server. About half of ICD-11 codes (47.76%) were mapped to at least one concept. The developed tool reached a global precision of 0.98 and a recall of 0.66. Lexical methods are powerful methods to map health terminologies. Supervised and manual mapping is still necessary to complete the mapping.

Keywords. Terminology mapping; Semantics; Terminology as topic; Unified Medical Language System; Vocabulary, controlled

1. Introduction

The International Classification of Diseases (ICD) version 11¹ is a major revision of the ICD-10 which is widely used to code diagnoses in healthcare systems. Furthermore, the purpose of the Unified Medical Language System® (UMLS) [1] is to facilitate the development of computer systems that behave as if they "understand" the meaning of the health language. The process of terminology mapping consists of identifying identical (or approximately identical) concepts or relationships between terminologies [2]. Since 2007, the Rouen University Hospital (RUH) Department of Biomedical Informatics (DBI) has developed the HeTOP cross-lingual health termino-ontology server [3], which includes 75 terminologies (or ontologies) in 32 languages².

The objective of this work is to propose a mapping of ICD-11 to the UMLS Metathesaurus and to French terminologies which are not (yet) included in the UMLS.

2. Methods

French natural language processing tools and mapping algorithms were developed by the RUH DBI team to map health terminologies in French. These tools were used in previous works [3][5] and extended to link terms in multiple French health terminologies. This approach allows from a given term, to find a HeTOP concept with French (or English) terms that are most lexically similar to it.

¹WHO International Classification of Diseases, 11th Revision (ICD-11); <https://www.who.int/classifications/icd/en/> (Accessed September 5, 2019).

² <https://www.hetop.eu/>

3. Results

The RUH DBI automatic mapping tool has generated 144,823 ICD-11 mappings to the 75 terminologies integrated into HeTOP. Concerning mappings between ICD-11 and ICD-10, WHO has manually provided 12,767, whereas RUH DBI has provided 6,925. The intersection between WHO and RUH DBI is 3,492 mappings (respectively 27.35% and 50.43%). This French automatic mapping tool has provided at least one mapping for 28,521 ICD-11 distinct codes (using their preferred labels and its synonyms and acronyms) among 59,709 ICD-11 codes (47.76%). The Top 6 terminologies with the most mappings to ICD-11 are SNOMED CT, MeSH and NCIT, which is coherent with the size of these terminologies and their translations as well as their main objectives, respectively 326,927 (201,659 in French), 378,024 (including the MeSH concepts; 105,933 in French) and 148,215 (79,409 in French). Among the 144,823 automatic mappings from ICD-11 to the 75 terminologies integrated into HeTOP, 2,371 were manually supervised by one expert (SJD), using six relations types: EM (exact match), BTNT (broader than), NTBT (narrower than), RT (related), unknown and false. The total number of distinct ICD-11 codes manually curated was 464 (mean mappings number of 5.1 per code). 82% of these automatic mappings were validated in exact match. 15% were evaluated as “close” mappings (i.e. BTNT, NTBT, RT). Only 46 mappings (2%) were evaluated as false. Furthermore, among the 464 ICD-11 curated codes, 183 have no mappings to any HeTOP concept. On the other hand, the expert manually added new mappings to 26 distinct ICD-11 codes without any automatic mappings. Thus the false negative rate is estimated to $26/(183+26)=12.4\%$. 1,226 new mappings from transitive closure were also added whose 154 automatically validated as Exact Match. Those figures allow an estimation of the recall: $2,371/(2,371+1,226)=65.92\%$.

4. Discussion and conclusion

To the best of our knowledge, this is the first study to map the entire ICD-11 classification to terminologies in French. The quality of these mappings can be considered as very good, as 82% were evaluated as an “exact match”, and only 2% are false. However, the cover of such tool is relatively low (47.76% of all ICD-11 codes) as many labels are too precise or not based on a state-of-the-art terminological method.

Master Patient Index Standardization Patient Search Identification Service (PSIS) of the National Directorate of Health Information Systems (DNSIS) Argentina

Humberto F MANDIROLA BRIEUX^{a, b} Alejandro LOPEZ OSORNIO^a Martin DIAZ
MAFFINI ^a Miguel AMORESE^a and Daniel A RIZZATO LEDE ^a

^a Ministry of Health, Argentina

^b HL7 Argentina.

Abstract. Correct patient identification is the cornerstone for the proper implementation of electronic health records. Up to 20% of the registered patients are duplicated in most systems. Strong identification policies and robust systems can minimize such errors. In this poster we share the Ministry of Health recommendations for the Master Patient Index improvement using search algorithms.

Keywords. Master Patient Index, Electronic Health Records, Soundex, Levenshtein, Patient Search Identification Service

1. Introduction

One of the most serious problems for Master Patient Index (MPI) is duplication of data[1]. Conventional database systems generally use deterministic searches to find document numbers or patient names, leading to mistakes. When the person responsible for entering data in the MPI is unable to find the patient, she will reenter the information, thus creating a duplicate patient. Duplicated patients in the MPI poses the risk of the loss of data due to the fragmentation of information [4]. It is important to use Patient Search Identification Service (PSIS) to avoid these types of mistakes. By using algorithms for a probabilistic search with multiple data (name, surname, birthdate, id type and number, gender), it is possible to identify suitable candidate patients by a group of similar data[2]. PSIS allows us to identify potential similar candidates and provides significant advantages over conventional searches [3] keeping the MPI clean.

2. Materials and Methods

For our Model of PSIS we use a minimum set of patient data composed of six data points that are: **Surname** (first and following), **Name** (first and middle), **Gender**, **Document Type**, **Document Number** and **Birthdate**. We apply two combined algorithms, the first being phonetic (Soundex), the other comparative (Levenshtein).

PSIS makes the first search for candidates by using Soundex and the second level by the distance of Levenshtein’s algorithm and that allows us to find the patients candidates files, see figure 1

The variables that consider are the relative weight V, the distance of Levenshtein and the length of the text of the candidate L. The coefficient F is calculated with the formula $F = (L-D) / L$ and finally, the value of each variable is obtained by multiplying the weight V by the coefficient F. The sum of the 6 variables gives us the probability that the candidate is the wanted one, in this case, 73.75%. See figure 2

3. Results

In order to prove the advantages of the PSIS we compared the Traditional Database Search (TDS) with PSIS. Results showed that the PSIS we built was a substantial help. PSIS allows us to detect 350 duplications in an MPI that had 50.000 patients, compared to TDS detecting only 50 duplications.

4. Discussion

The PSIS significantly improves the discovery of duplicates in an MPI compared to that of TDS. PSIS searches identify 88% more duplicate candidates than those found in TDS.

5. Conclusion

If we make a mistake in the document number by a single digit, using conventional searches (TDS), the patients cannot be found. Using the Levenshtein distance algorithm allows us to identify that the number is very similar to the one searched often indicating a simple human error in data entry.

Near Real Time Feedback of Seasonal Influenza Vaccination and Virological Sampling: Dashboard Utilisation in a Primary Care Sentinel Network

Harshana LIYANAGE^a, Oluwafunmi AKINYEMI^a, Sameera PATHIRANNAHELAGE^a, Mark JOY^a and Simon DE LUSIGNAN^{a,b,1}

^a*Nuffield Department of Primary Health Care Sciences, University of Oxford, UK*

^b*Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC), London, UK*

Abstract. Near-real time feedback on data quality allows clinicians and data managers at general practices to collectively contribute to improving the reliability of observational data. We report features of an enhanced dashboard used for virological surveillance after the first season of utilisation. Time-series analysis performed on dashboard usage data from 68 general practices (denominator = 722,409) indicated utilisation patterns that correlated to influenza vaccination in general practices. Near real time feedback via a dashboard may improve data quality and possibly vaccine uptake.

1. Introduction

Influenza contributes significantly to the burden of disease morbidity and mortality worldwide[1]. Virological surveillance helps identify the predominant strain in circulation; it also provides an understanding of the pattern of disease transmission and planning towards pandemic preparedness. We report enhancements made to the Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC) virological surveillance dashboard and usage analysis after its first use in surveillance activities during a complete influenza season (2018/2019) [2].

2. Methods

We obtained data for the dashboard from the RCGP RSC database which includes pseudonymised health care records of individuals registered with general practice network in England (68 practices that participated in the virology swabbing scheme with an overall denominator of 722,409) [3]. These practices provided nasal and nasopharyngeal swabs for confirming influenza within a laboratory setting. We enhanced the dashboard for the 2018/2019 influenza season by adding comparative assessment

¹ Corresponding Author: Simon de Lusignan, Nuffield Department of Primary Health Care Sciences, University of Oxford, UK; E-mail: simon.delusignan@phc.ox.ac.uk.

episode type recording customised for each given practice. We carried out time-series modelling on the dashboard data (from July 2018 to March 2019) using the R statistical package (version 3.6.1) and compared with seasonal influenza and flu vaccination trends.

3. Results

The participating general practices accessed the dashboard particularly between October 2019 and March 2020 which is the peak of the flu season. General practices typically start conducting flu clinics at the beginning of October (in any given year) and are held weekly for about 8 weeks. We observed a peak in dashboard access following the initial flu vaccination campaign and a 2nd peak in dashboard access soon after the increase of Influenza-like (ILI) incidence at the beginning of January 2019. Results of the Granger causality test indicated that there is evidence that after controlling for the lagged effects of flu vaccination counts, lagged visits carry predictive power ($p < 0.001$) for flu vaccinations. There is no evidence that the same applies between ILI counts and visits.

4. Discussion

Trend analysis may explain the periods when dashboard utilisation increases across the sentinel network. The results indicate that dashboard use increases shortly after influenza vaccination campaigns with the peak seen during influenza circulation not being statistically associated.

5. Conclusion

Findings of this study together with feedback from user surveys helps the RCGP RSC to understand the peaks of dashboard use, and which areas of the dashboard have more user engagement that could benefit from further development. Dashboard feedback may have a role in improving data quality and prompting vaccine administration.

Neural Networks for Cause of Hospitalization and Final Cause of Death Extraction from Discharge Summaries

Francisco E. PEPPER^{a,1}, M. Belén CARDONE^b and Santiago ESTEBAN^a

^a*Family and Community Medicine Division, Hospital Italiano de Buenos Aires, Argentina*

^b*Instituto Universitario Hospital Italiano de Buenos Aires, Argentina*

Abstract. Determining the cause of death of hospitalized patients with cardiovascular disease is of the utmost importance. This is usually recorded in free text form. In this study we aimed to develop a series of supervised natural language processing algorithms to extract cardiovascular causes of hospitalization and final causes of death.

Keywords. Natural language processing, discharge summaries

1. Introduction

Determining the cause of death of hospitalized patients with cardiovascular disease is of the utmost importance in order to take measures and thus improve the quality of care of these patients and prevent preventable deaths. Even though hospitalization causes and final causes of death can be recorded in structured form within electronic medical records (EMR), they are usually entered in free text form inside discharge summaries[1]. In this study we aimed to develop a series of supervised natural language processing algorithms in order to extract cardiovascular causes of hospitalization and final causes of death.

2. Methods

We manually reviewed a random sample of 6161 discharge summaries of patients who died between January 1st, 2005 and December 31st, 2016 at Hospital Italiano de Buenos Aires, Argentina. All annotations were carried out by one family physician. Patients' cause of hospitalization was initially classified as cardiovascular causes vs non-cardiovascular. Cardiovascular causes were further classified into ICD-10 codes. These comprised 21.3% (n = 1316) of the total sample. We defined three classification tasks: two related to cause of hospitalization (cardiovascular vs non-cardiovascular; specific type of cardiovascular cause) and one related to final cause of death. Causes of hospitalization were annotated as cardiovascular vs non-cardiovascular and then as ischemic cardiac diseases, cerebrovascular diseases and other causes. Final causes of death were classified in six categories namely, cardiogenic/hypovolemic shock, septic shock, cerebrovascular diseases, renal failure, malignant neoplasms and other causes. The sample was randomly split into training (80%), validation (10%) and test sets (10%). We then trained three different algorithms for the three classification tasks and evaluated their performance on the test set. For the three algorithms different architectures were

¹ Corresponding author email francisco.peper@hospitalitaliano.org.ar

tested (Support vector machines, logistic regression, k-nearest neighbors, XGBoost, Random Forests, C5.0, GBM and different neural network architectures. For the three cases, neural networks showed the best results in the validation set. The final architecture consisted of a bi-directional long-short-term-memory recurrent neural network with attention mechanism, with two stacked dense layers. Words were represented using FastText word vectors.

3. Results

For the first classification task (algorithm 1), the performance on the test set resulted in an accuracy of 0.9546 (95% CI 0.9351, 0.9696), Recall of 0.979, Precision of 0.9225 and F1-score of 0.895. Table 1 shows the individual metrics per category for the second and third algorithms.

Table 1. Performance of the second and third algorithms on the test set.

Algorithm 2						
		Ischemic cardiac diseases (I20-25)	Cerebrovascular diseases (I60-I69)		Other cardiovascular causes	
Recall		0.67	0.967		1	
Precision		1	1		0.9	
F1-score		0.815	0.96		0.95	
Algorithm 3						
	Cardiogenic hypovolemic shock (R57.0/R57.1)	Septic shock (R57.2)	Cerebrovascular diseases (I60 - I69)	Renal failure (N17-N19)	Malignant neoplasms (C00-C97)	Other causes
Recall	0.94	0.47	0.76	0	-	0
Precision	0.79	1	0.59	-	-	-
F1-score	0.86	0.64	0.66	-	-	-

4. Discussion

Even in this low sample size scenario, neural networks outperformed classical machine learning algorithms for text classification. Nevertheless, performance dropped significantly as the sample size was reduce for algorithms 2 and 3 and also as the number of classification categories increased.

5. Conclusions

We developed three NLP algorithms for information extraction regarding cause of hospitalization and final cause of death from discharge summaries.

Numerical Analysis of Conventional Air Pollutants and PM₁₀ Concentration Affected to Respiratory Disease Patients in Bangkok, Thailand

Wisit THONGKUM^{a,1} and Santisith KHIEWKHERN^a

^a*Faculty of Public Health, Mahasarakham University, THAILAND*

Abstract. Ambient air pollution is a major cause of death and disease globally. The linear regression between respiratory disease patients, PM₁₀ and other criteria pollutants were used in this study. Among respiratory disease patients and CO was statistically significant with P-value of <0.01 ($r=0.198$, 95% CI=48.74 - 288.16). As for respiratory disease patients and NO_x was statistically significant with P-value of <0.01 ($r=0.190$, 95% CI=1379.74 – 9241.43).

Keywords. Air pollutants, PM10, Respiratory disease

1. Introduction

Air pollution kills an estimated 7 million people worldwide every year. Air pollution resulting from traffic is a major problem in many cities in Asia, including Bangkok, Thailand. This pollution originates mainly from incomplete fossil fuel combustion, transportation, and construction (Ruchirawat et al, 2007). The concept of this study is utilizing the data obtained from the current conventional air monitoring station in Bangkok to analyze conventional air pollutants and PM₁₀ concentrations affected respiratory disease patients in this area.

2. Data analysis and Method

2.1. Data collection and Analysis

The air monitoring data used in this study were from Jan 2013 to Dec 2018. Conventional air pollutants and PM₁₀ were monitored at 3 monitoring sites in The Bangkok Metropolitan area. The data of respiratory disease patients in this study from Jan 2013 to Dec 2018. The respiratory disease was bronchitis, emphysema, chronic obstructive pulmonary disease, and asthma. This study was collected from 3 hospitals. The correlation coefficient and linear regression analysis were used to determine a potential correlation between conventional air pollutants and PM₁₀ concentrations and number of respiratory diseases patients. Independent variables were conventional air pollutants and PM₁₀ concentrations. The dependent variable was respiratory disease patients.

¹ Corresponding Author; E-mail: santisith.k@msu.ac.th.

3. Results and Discussions

3.1. Diurnal variation of PM₁₀ concentration and respiratory disease patients

The concentration of PM₁₀ shows a similar type of variation as a decrease from May to Sep an increase from Oct to Dec and Jan to Apr of each year. This is probably because of the enhance emission from traffic and seasonal variation (Aurangojeb M., 2011). The number of respiratory disease patient’s tendencies increase from Jan 2013 to Dec 2018. The number of respiratory disease patient’s tendency decrease from Jan 2013 to Apr 2017 after that increase to Dec 2018. The concentration of PM₁₀ shows a similar type of variation as a decrease from May to Sep an increase from Oct to Dec and Jan to Apr of each year. The number of respiratory disease patients slightly varies from Jan 2013 to Dec 2018. After the government of Thailand has taken various roles to mobilize its resources for haze management in the second stage from 2011 to 2019.

3.2. The correlation coefficient and linear regression analysis

The Pearson’s product moment correlation coefficient (r) was used to determine the strength of association between a pair of variables, to test the relationship between these variables and to test whether the association is greater than could be expected by chance (Rummasak T., 2019). Among respiratory disease patients and CO was statistically significant with P-value of <0.01 (r=0.198, 95% CI=48.74 - 288.16). As for respiratory disease patients and NO_x was statistically significant with P-value of <0.01 (r=0.190, 95% CI=1379.74 – 9241.43) presented in Table 1.

Table 1. Linear regression analysis of respiratory disease patients, PM₁₀ and other criteria pollutants

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	95.0% Confidence Interval for B	
	B	Std. Error	Beta			Lower Bound	Upper Bound
2 (Constant)	366.33	110.14		3.326	.001	149.22	583.45
CO	168.45	60.73	.198	2.774	.006	48.74	288.16
NO _x	5310.59	1994.17	.190	2.663	.008	1379.74	9241.43

4. Conclusions

The concentration of PM₁₀ shows a decrease from May to Sep an increase from Oct to Dec and Jan to Apr of each year. The number of respiratory disease patient’s tendency decrease from Jan 2013 to Apr 2017 after that increase to Dec 2018. The linear regression between respiratory disease patients, PM₁₀ and other criteria pollutants were used in this study. Among respiratory disease patients and CO, respiratory disease patients and NO_x were statistically significant.

Patients' Experience and Assessment on the Transition from Paper to Electronic Medical Records

Carolina ARMAGNAGUE THIVANT^a, Santiago ESTEBAN^a
Analia J. BAUM^a

^a*Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina.*

Abstract. By the implementation of the EMR in the Primary Care Centers of the City of Buenos Aires, it has been claimed that there is a need to obtain systematic and accurate information about the assessment that patients have about such incorporation. A qualitative research has been carried out in order to answer this query.

Keywords. Doctor-patient relationships; Electronic medical records; paper health record.

Introduction

The *Health Information Systems Office* at the Buenos Aires City health ministry EMR launched the implementation of the EMR in the First level of Health Care in 2016. This comprises 44 primary care health centers (PCHC). In this context, we have recognized the need to obtain systematized and accurate information about patients' experience during the transition from the paper health record (PHR) to the EMR.

Methods

We conducted a qualitative exploratory study. We used semi-structured interviews of a convenience sample of patients. The participants selected were men and women over 18 years of age who at least once had been treated in a center where the EMR had been implemented. Three PCHC were selected as these were the first to implement the EMR. Interviews were audio-recorded and transcribed verbatim. The dimensions were extracted into a database table and categories were created depending on similarity and repetition among relevant segments to approach the problem.

Main outcomes

We interviewed 29 patients. The sample was divided based on age: "Young" (18<30); "Adult" (30<60); "Older Adult" (60<). Most of the interviewees considered that the

EMR is the same or better than the PHR. In relation to EMR's attributes, they highlighted: practicality, exhaustiveness, speed, and the possibility of being in the network. As to the effects of the EMR implementation on the medical visit, they considered that it represents a substantial help to the professional. It also avoids repetition of information and allows for focusing directly on the reason for the medical visit, providing an integral view of the patient. With respect to the PHR, interviewees considered that the process involved in the PHR was more tedious or slower. It can be observed that the EMR prevails over the PHR. Nevertheless, patients in the three age groups insisted on the importance of having an updated backup copy in paper. Patients had a positive opinion towards health professionals' advanced use and skills of the EMR. They believe that health professionals are satisfied with the EMR implementation and that the time required to register information into the EMR is reasonable. As for the young and the adult groups, it can be observed that there is an interest in sharing the screen with the professional in order to help register the information. Instead, the older adults' group stated that they do not find it necessary to see the screen as they "trust" in the professional. As emerging topics, the interest of young people in the possibility of reprinting lost prescriptions or vaccination certificates appeared; at the same time, they showed interest in having access to the EMR at home.

Discussion

Most of the interviewees viewed that the EMR is the same as the PHR while others considered that the former is better. This result led us to infer that the EMR implementation has not been experienced as an interruption or breakdown in the attention, but instead as a continuity of their health care. As can be seen from the results, patients consider that professionals have a positive assessment on the EMR and that they master this new system. As other studies reveal, the professional's positive attitude towards the use of the EMR can impact on the patient's assessment and experience [1].

The sample was divided based on age because the team considered that differentiation could directly influence on the naturalization of digital devices to daily life. In effect, the results obtained in relation to the young people would lead to think in new user generations of the health system with an active position and willingness to gain more participation. Unlike that perspective, within older adults, it prevails the idea that the doctor represents a figure of power and authority that hinders the possibility of thinking in a method of cooperative and symmetric attention.

Conclusion

Patients generally express a positive or neutral perception of the EMR. There are not elements to infer a loss of continuity of care.

Personal Health Record (PHR) System in Portable Health Clinic

Rafiqul ISLAM^a, Kimiyo KIKUCHI^b, Yoko SATO^c, Rieko IZUKURA^a,
Fumihiko YOKOTA^b, Mariko NISHIKITANI^b, Raisa TASNEEM^d,
Nazneen SULTANA^d, Ashir AHMED^e and Naoki NAKASHIMA^a

^bInstitute of Decision Science for Sustainable Society, Kyushu University, Japan

^cDepartment of Medical Science, Kyushu University Hospital, Japan

^dGrameen Communications, Dhaka, Bangladesh

^eDepartment of Advanced Information Technology, Kyushu University, Japan

Abstract. Personal Health Record (PHR) is not just the collection of personal health data but also a personal healthcare and disease management tool for the individual patient as well as a communication tool with the medical staff. Moreover, recently PHR has been considered an indispensable tool for patient engagement in the area of non-communicable diseases (NCDs) and has gained importance. Like many other developing countries, the growth of NCDs is very high in Bangladesh. Portable Health Clinic (PHC) system has been developed there with a focus on NCDs and PHR is there from the beginning. This study for the standardization of PHR system of PHC with the reference of the PHR proposed by Japanese Clinical Societies could be a reference work for the national PHR system development in the country.

Keywords. Personal Health Record, Portable Health Clinic, Standardization

1. Introduction

Personal Health Record (PHR) has been getting popular as an important supportive tool for providing better healthcare service by the medical professionals. These days there are many applications for smartphones that help to manage personal clinical data about NCDs generated in clinics and drugs dispensed by pharmacies. This is the simplest form of PHR. However, a standard PHR system is expected to manage information regarding an individual's vital signs, physical exercise, behavior, and location at home or at the office using built-in sensors in the smartphone or using sensor networks based on internet of things (IoT) technology. Patient will have access to monitor this personal health/medical data and express personal opinion for the progress of the treatment. This helps the physician to be confident to change the policy and to intervene [1].

2. Portable Health Clinic

Portable Health Clinic (PHC) system was designed in 2010 by Grameen Communications, Bangladesh in a joint collaboration with Kyushu University of Japan as a telemedicine

based healthcare system [Figure 1]. Later some new modules have been added to this modular system for satisfying patients demand for serving secondary level of treatments in Eye (ophthalmic) Care and Maternal & Child Healthcare (MCH) [2].

PHR service has been there as a personal service to the patients from the beginning. The patients can access to their own data on smartphone, monitor and share their feedbacks to the physicians if they need to receive any consultancy.

3. Standardization of PHR

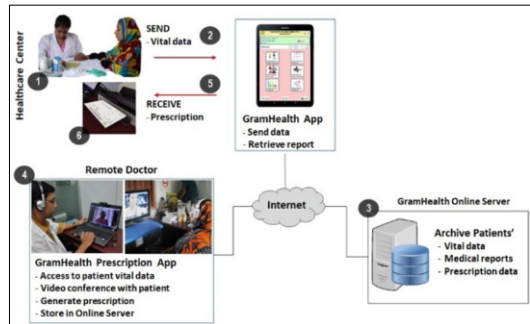

Figure 1 Work Flow of PHC System

As the content of the PHR of PHC system was developed independently, there are always some issues for the use of this PHR data by medical professionals of other countries in terms of clinical data items and measurement units. The clinical data items in PHR varies country to country. Thus, the need of standardization of the PHR has always been felt for data portability and to pass interoperability.

Recently six major Japanese clinical societies jointly proposed a set of 41 items as standard for PHR for NCDs in Japan after years of investigations [3]. There was unanimous consensus, then installed and expanded allover Japan. This PHR protocol is being used in various top PHR service provider (app company) in Japan.

This research aimed to standardize PHC's PHR system considering this Japanese PHR system as a standard and passed the interoperability for NCDs. In case of Eye Care, the ophthalmic image in JPEG format has been added in PHR for diseases prediction by AI based image analysis. In case of MCH, hemoglobin measurement and fetus beat per minute has been added as these are the major issues for mother and child respectively.

4. Conclusion

Development of PHR system and its standardization is very much desired for wider scope of quality healthcare services in Bangladesh from medical service point of view. This work of PHR standardization of PHC system is just a step forward in this direction.

Persuasive eHealth to Support Home Rehabilitation of the Elderly After a Hip Operation: An Explorative Approach

Laurence ALPAY^{a,1} and Ybranda KOSTER^a

^a Medical Technology Group, Inholland University of Applied Sciences

Abstract. Home rehabilitation after a hip operation can be daunting for the elderly. Lack of motivation to exercise and being insecure in the recovery process are common barriers. Personalized eHealth can help to ensure that the patient exercise efficiently, filling the gap between treatment in the practice with the physical therapist and practice at home.

Keywords. eHealth, home rehabilitation, elderly

1. Introduction

The elderly population is growing worldwide, and osteoarthritis amongst this group is common, often resulting in a joint prosthesis¹. The stay in the hospital after such an operation is very short. Rehabilitation after discharge from the hospital takes place with a physical therapist. The usual after-care is about exercising to improve the mobility of the hip / knee. Instructions are usually given in the form of folders of videos. However, physical therapists see a gap between treatment in their practice and practice at home. Furthermore, patients are not always motivated enough to exercise at home and are unsecure in what they do. The use of eHealth to support the patient's rehabilitation at home is limited. Sensor technologies for example are used to collect quantitative information about joint recovery². The research reported here focuses on exploring the design of a persuasive eHealth solution, for effective rehabilitation at home.

2. Method

In order to design a persuasive eHealth solution, we use the methodology we developed based on the CeHRes framework and other models for persuasive design and behavioral change³. This methodology begins with a contextual inquiry, resulting into prototyping and finally implementation. Persuasive features and triggers for motivational behavior are throughout the design process incorporated into the eHealth solution. Three groups of 3rd and 4th year bachelor students (4 to 5 students per group) worked for a period of 20 weeks with the Medical Technology Research Group on this project. One group

¹ Corresponding Author: Laurence Alpay, Inholland University of Applied Sciences, Bijdorplan 15, 2015 CE Haarlem, The Netherlands; E-mail: Laurence.alpay@inholland.nl

consisted of informatics students from InHolland University of Applied Sciences and two other groups consisted of a multidisciplinary team from Rotterdam University. Students used a fictive casus reflecting a real-life situation. We chose the approach of student's participation and action research in order to explore various proofs of concept and to provide students the opportunity to experience a healthcare setting and to think out of the box with other disciplines.

3. Results

The designing of an eHealth solution focused mainly contextual inquiry, requirements and prototyping. Formative evaluation was carried out with the targeted groups. Each group provided a proof of concept developed in co-creation with the targeted group and physical therapists. Researchers from the Medical Group acted as eHealth experts. Figure 1 shows a paper prototyping from one group during contextual inquiry, and a developed solution to ensure that the exercises are done correctly from another group. Students used Fogg's Behavior Grid to determine the kind of behavior change that was needed to optimize the rehabilitation process at home. In the design of their eHealth solutions they used the principles of persuasive design as described by Oinas Kukkonen to determine which persuasive elements should be used.

Figure 1. Prototype examples

4. Discussion and Conclusions

Home rehabilitation after a hip or knee operation often remains a challenge for a growing number of elderly and limit participation and self-management. Exploring various eHealth proof of concepts based on persuasive features and behavioral change can help to tune to a more personalized solution. Students' participation is an added-value for the healthcare setting and for providing input to further research in this area.

Physicians' and Pharmacists' Opinions Regarding the e-Prescription Systems

Giorgos NIKOU¹ and Parisis GALLOS

*Department of Computer Science and Biomedical Informatics,
University of Thessaly, Lamia, Greece*

Abstract. The e-Prescription systems are modern and efficient prescribing tools which can affect the quality of the healthcare services. The aim of this study is to evaluate the e-Prescription systems in Greece based the users' opinions. The survey was conducted in 2019 among 157 randomly selected healthcare professionals through an on-line survey tool. The 51.2% of the sample were pharmacists and 48.8% physicians. 80.7% believe that the e-Prescription systems are reliable. More than the half of the professionals has the view that the e-Prescription systems are useful. Regarding to the ease of use, the e-Prescription systems, seem to can not fulfill sufficiently the participants' requirements.

Keywords. Electronic Prescription, Evaluation Study

1. Introduction

The electronic prescription systems could be assumed as modern and efficient prescribing tools for drugs and other medical product or services [1]. The usage of the e-Prescription systems has significantly reduced the errors during the prescription process as well as, led to a better control of the health costs [2]. The evaluation of these systems seems to be important as it can affect the system functionality and the users' satisfaction [3,4]. Today, two e-prescription systems are in use in Greece. The IDIKA's system is used for drug and diagnostic tests prescription and the EOPYY's system for all the other prescribing items. The aim of this pilot study is to record the physicians' and pharmacists' opinions regarding the above e-Prescription systems in order to evaluate the systems' reliability, usefulness and ease of use.

2. Methods

To achieve the aim of this study, a self-developed questionnaire was used. The questionnaire included questions about the participants' age, profession, years of experience, their opinions regarding the mistakes during the prescription process due to the systems, the reliability, the usefulness and the ease of use of the e-prescription systems, and the participant's cost of usage for the e-prescription services. The survey was conducted in Greece in 2019 among 157 randomly selected Physicians and

¹Corresponding Author, Giorgos Nikou, Student at the Department of Computer Science and Biomedical Informatics, University of Thessaly, Lamia, Greece; E-mail: gnikou07@gmail.com.

Pharmacists through an on-line survey tool. Descriptive statistics and correlations between the participants' profession and their opinions were examined using SPSS.

3. Results and Discussion

After the statistical analysis, the 51.2% of the sample were pharmacists and 48.8% physicians. The mean of the age was 43.46 years old. About the professional experience, the 23.3% of them have more than 10 years. As 39% of all mistakes on the prescription process are due to the e-Prescription system malfunctions, the 79.1% of the participants believe that the last two years the number of errors, due to system malfunctions, was decreased. Meanwhile, the 80.7% think that the e-Prescription systems are reliable. For IDIKA's system, the 86% of the participants assumes that the system is useful and 73.8% accepts that it is easy to use. On the other hand, for the EOPYY's system, the 56.9% of the participants believe that the system is useful and only 22.7% thinks that it is easy to use. Additionally, the mean of the annual cost of usage for the e-prescription services is 554.78 euro. Comparing the participants' profession with their opinions regarding the e-Prescription systems, all comparisons were not confirmed ($p > 0.05$), except the comparison between the profession and the perceived ease of IDIKA's system use ($p < 0.01$). Finally, the pharmacists believe that the IDIKA's prescription system is easy to use, way more than physicians. No other differences in opinions between physicians and pharmacists were found.

4. Conclusions

According to the aforementioned results, although the participants believe that a large percentage of the prescription errors are related to the e-Prescription systems, they trust the systems, and these systems are assumed reliable by the majority of the participants. The majority of the professionals have the view that the e-Prescription systems are useful. Regarding to the ease of use, the e-Prescription systems, does not fulfill sufficiently the participants' requirements and on one of the system, pharmacists seem to be more familiar with the systems usage rather than the physicians. Future work may include a wider scale survey using structured and valid measuring tools in order to record more accurately the healthcare professionals' opinions about the e-Prescription systems on international level.

Abstract. Since a French organization (2016) has defined “the territorial hospital groupings”, public hospitals must share medical-economic knowledge and decision-makers expect prospective analyses. PoleSat aims, quick hospital-catchment area modellings, completed by population analyses. Modellings are based on “diagnostic and interventional vascular catheterizations” acts and Nouvelle-Aquitaine, and they are carried out 3 times, through the graphical user interface’s main-setting values, coupled with 3 activity-scenarios. Scenario results cannot confirm the NA02-Atlantique’s H0. The experts have approved PoleSat’s method as a robust help-tool; therefore they project to repeat its usages.

Keywords. Models, Gravitation, Geographic Mapping, Management Information Systems, Diagnosis-Related Groups (DRG), Decision Making, Computer-Assisted

1. Introduction

Since a French organization (2016) has defined “the territorial hospital groupings THGs” i.e. a new sanitary level for health management, public hospitals must share medical-economic information [1]; also, keeping up with this movement, health decision-makers need prospective activity/recruitment analyses; thus, to help decision-makers, PoleSat tailored IT tool [2] aims quick-easy modelling of hospital catchment area (CA), completed by population analyses (per scenario). Two main hospital centers (CH) are targeted to predict the activity transfer impacts between Rochefort - and

¹ Anne Quesnel-Barbet, CHU of Lille, MRRC, 6 rue du Pr Laguesse, CS 70001, 59037 Lille cedex, France; E-mail : aquesnel@univ-lille.fr

Saintes – CH, and to accept/reject the *NA02 – Atlantique 17 THG's* recruitment hypothesis H0.

2. Materials and methods

PoleSat allows to upload its own health *ready-input file*, [2] and to ensure a general data protection regulation compliance. Other variables are added [3] to obtain localization & geographic limits. Modellings are applied on “diagnostic and interventional vascular catheterizations (DIVC)” activity from DRG-PMSI 2018 [1], and concern 2 Nouvelle-Aquitaine's THGs.

Initial, transfer, and removal activity-scenarios are considered to confirm/refute H0: “High positive activity gain of 100% is expected for Saintes, under a transfer of 617 acts from Rochefort - to Saintes”. Modellings are carried out 3 times, through the graphical user interface's main-settings (P1: 2, P2: 54, P5: 2, & P8: 15), coupled with PMSI-ready-input files tied to each activity-scenario.

3. Results

The 3 activity-scenario modellings are presented in Figure 1.

Figure 1. a- “initial scenario”, Rochefort’s CA inside a purple-ellipse appears in light-green. b- “removal scenario”, Rochefort’s CA has disappeared & almost all its CA is eaten by La Rochelle’s CA. c- “transfer scenario”, inside a red-circle Rochefort’s activity transfer to Saintes. Saintes’ CA has weakly increased in “c” in comparison with the similar area in “b”

4. Discussion & Conclusion

Each hospital activity around Rochefort increases proportionally to the covered-population growth; also, the transfer does not lead to the expected decrease of DIVC in Rochefort’s area; thus, La Rochelle could attract 2 to 3 times more patients than Saintes; therefore, the outcomes cannot confirm H0. Reduce activity leak of Saintes appears evident for the experts, which have validated Polesat (distance & mass) as a robust help tool, and project to repeat its usage to other health planning cases.

Predicting Diagnosis Code from Medication List of an Electronic Medical Record Using Convolutional Neural Network

Jakir Hossain Bhuiyan MASUD^a, Ming-Chin LIN^{a,b,c,1}

^a*Graduate Institute of Biomedical Informatics, College of Medical Science and Technology, Taipei Medical University, Taipei, Taiwan*

^b*Division of Neurosurgery, Department of Surgery, Shuang-Ho Hospital, Taipei, Taiwan*

^c*Taipei Neuroscience Institute, Taipei Medical University, Taipei, Taiwan*

Abstract. Automated coding and classification systems play a role in healthcare for quality of care. Our objective was to predict diagnosis code from medication list of electronic medical record (EMR) using convolutional neural network (CNN). We collected the clinical note from outpatient department (OPD) of Wanfang hospital, Taiwan of 2016 and used three physicians from three departments. The dataset was split into two parts, 90% for training and 10% for test cases. We used medication list as input and International Statistical Classification of Diseases 10 (ICD 10) code as output. After data preprocess, we used word2vector CNN to predict ICD 10 code. This study shows all the three physicians from three departments achieved better performance. The best performance of model was a physician from cardiology department achieved precision 69%, recall 89% and F measure 78%. We need to include more component such as text data, lab report for evaluation.

Keywords. Clinical note, International Statistical Classification of Diseases 10 (ICD 10), medication, convolutional neural network

1. Introduction

Electronic medical record (EMR) is routinely collected heterogenous data. Each record should have complete information of problem list to establish diagnosis and abnormal findings [1]. However, it is hard to create accurate predictive model, because of heterogenous data, data quality and label availability [2]. Medical coder put International Statistical Classification of Diseases 10 (ICD 10) code manually in the EMR and it's labor intensive and time consuming. A study used 17 conditions for identifying problem lists of patients based on medication and laboratory results [3]. Natural language processing (NLP) uses for different problem transformation approaches and employing suitable label calibration and ranking methods [4]. Pre-trained word vectors use for sentence-level classification on CNN [5]. Our aim was to explore whether we can automatically assist physician to predict diagnosis code from medication list of EMR using CNN.

¹ Corresponding author: E-mail: arbiterski@gmail.com

2. Method

Dataset: This study is a retrospective cohort of patients. We collected clinical notes of outpatient department (OPD) from the EMR of Wanfang Hospital, Taiwan of 2016, consists of SOAP, medication, diagnosis lists. The total medical records were 10,364 where 9,583 (90%) for training and 781 (10%) for test set that include three Physicians.

Experimental setup: We consider the task as multi-label classification problem, where the input is medication list and the output is the ICD-10 label of clinical note. We implemented word embedding word2vector (w2v) CNN for multi-label classification task using python, Keras. We used Sigmoid activation function at the end of CNN. We used ranking method for getting top 10, top 5 diagnosis using the dataset. This ranking can identify the best diagnosis chronologically. Initially it takes the tokenization, use w2v and then use CNN. CNN used with Keras and weight parameters are optimized using Adam method that is a variant of the stochastic gradient descent (sgd) algorithm.

Evaluation: The evaluation was done by precision, recall and F measure.

3. Result

Our study shows the best performance of CNN model for a physician from cardiology department as precision, recall and F measure were 69%, 89% and 78% respectively. The predicted ICD 10 using probability that identify the ranking where E782 Mixed hyperlipidemia is the top (probability 0.9972247) of a diagnosis list.

4. Conclusion

We find better model performance as well as better ICD 10 prediction chronologically through probability. However, we need to explore the evaluation by all physicians and include text data, lab report in future tasks.

Abstract. Out-of-hospital cardiac arrest (OHCA) is an important public health problem, with very low survival rate. In treating OHCA patients, the return of spontaneous circulation (ROSC) represents the success of early resuscitation efforts. In this study, we developed a machine learning model to predict ROSC and compared it with the ROSC after cardiac arrest (RACA) score. Results demonstrated the usefulness of machine learning in deriving predictive models.

Keywords. Out-of-hospital cardiac arrest, ROSC, machine learning, random forest

1. Introduction

The return of spontaneous circulation (ROSC) serves as an indicator of the success of early resuscitation in out-of-hospital cardiac arrest (OHCA) patients. Given the global burden of OHCA and disparity among healthcare systems, a simple tool is needed to enable comparison of different EMS systems worldwide. The ROSC after cardiac arrest (RACA) score [1] developed in Germany is one solution, which uses variables that are available after EMS arrival to assess the probability of ROSC through logistic regression. In this study, we aimed to create a machine learning model to predict ROSC.

2. Method

We used the data collected from Pan-Asian Resuscitation Outcomes Study (PAROS) [2]. The data consists of OHCA victims recruited between January 2009 and December 2012 from Japan, South Korea, Malaysia, Singapore, Taiwan, Thailand, and United Arab Emirates (UAE). In this study, we excluded paediatric cases (<18 years old), non-EMS transported cases, and those with a “do not resuscitate” order. We used random forest

and following variables to build a prediction model: gender, age, cardiac arrest aetiology, witness, location, initial rhythm, bystander cardiopulmonary resuscitation (CPR), and EMS arrival time. We randomly selected 70% data for random forest model training and the remaining 30% data for testing the model and the RACA score.

3. Results

A total of 63,059 patients were used in our analysis, of which 5,190 (8.2%) patients had ROSC at scene or en route to ED. Figure 1 shows receiver operating characteristic (ROC) curves generated by the random forest model and the RACA score. Area under the ROC curves were 0.76 and 0.73 for random forest and RACA score, respectively.

Figure 1. ROC curves of the random forest model and the RACA score.

4. Discussion

Our study showed that a machine learning model (random forest) outperformed RACA score in predicting ROSC among OHCA patients. The results demonstrated the power of machine learning in deriving predictive tools. Overall, the discriminatory abilities of both machine learning model and RACA score (0.76 and 0.73 AUC) were comparable to the original RACA score (0.73 AUC) on German registry patients. Our study proved the applicability of the RACA score in Pan-Asian countries and illustrated the possibility of applying machine learning algorithms in developing new predictive tools.

5. Conclusion

Machine learning is worthy of further investigation in developing powerful predictive tools for OHCA and other medical applications.

Predictors of Hospital Admissions Based on Routinely Collected Everyday Observations in a Community Care Setting

Mads Nibe STAUSHOLM^{a,1}, Pernille Heyckendorff SECHER^a and Ole Kristian HEJLESEN^a

^a*Department of Health Science and Technology, Aalborg University, Denmark*

Abstract. The aim of this study was to identify predictors for hospital admissions in community-dwelling adults based on routinely collected community data. Univariate logistic regression analyses were performed to assess each variable's ability to predict preventable and all cause hospital admissions.

Keywords. Prediction, primary health care, elderly, home care, hospital admission

1. Introduction

Population ageing challenges the existing healthcare systems as the older population are at higher risk of chronic diseases that require long-term care (1), and more frequent hospital admissions (2). Consequently, avoiding unnecessary hospital admissions have become a priority, as both the primary- and secondary healthcare sector cannot keep up with the rising demand (3). The Triage Changing Table has been recommended by The Danish Health Authority for early detection of acute events and prevention of preventable hospital admissions based on home care providers' everyday observations of clients' health states (4,5). No studies have examined the association between data obtained from the Triage Changing Table Database and hospital admissions. The aim of the present study was to identify predictors for preventable and all cause hospital admissions in community-dwelling adults based on everyday health state observations.

2. Methods

First paragraph. Data was retrospectively collected from The Patient Administrative System used in the North Denmark Region, which includes information about hospital admissions, and The Triaged Changing Table Database. 4,410 subjects aged 65 or above residing in Aalborg Municipality, Denmark, were included in the study. The outcomes were preventable and all cause, acute hospital admissions defined as an unplanned overnight stay in hospital. Prior to each acute hospital admission, we defined a prevention, event, and control period with length of three, 14, and 14 days, respectively. A total of 279 and 261 features were constructed from the Triage Changing Table variables for the

¹ Corresponding Author.; E-mail: mns@hst.aau.dk.

preventable and all cause hospital admission analyses, respectively. Univariate logistic regression analyses were performed to assess each variable's ability to predict the outcome. Five-fold cross-validation was applied to reduce the risk of overfitting and increase generalizability to new data.

3. Results

A total of 68 control and event period pairs from 53 subjects was included in the all cause hospital admission analysis. 19 control and event period pairs from 18 subjects were included in the preventable hospital admission analysis. The most discriminative predictor variable for all cause hospital admissions was the difference in total sum of item codes between the first and last registration in each period (OR = 1.20; 95% CI = 0.94, 1.55; $p = .14$; $AUC \pm STD = .60 \pm .12$). For the preventable hospital admissions, the most discriminative predictor variable was the number of Triage Changing Table registrations (OR = 1.05; 95% CI = 0.92, 1.19; $p = .48$; $AUC \pm STD = .65 \pm .16$). No predictors showed statistically significant associations with the outcome.

4. Discussion

This study used only routinely collected data extracted from administrative databases in a community care setting, which compared to self-reported data tends to have greater predictive performance (6). The reported AUCs indicate some discriminative potential, however, no variables had statistically significant association to the outcome, which may be due to the relatively low sample sizes. The current data segmentation strategy limited the number of subjects and control/event periods. A less restrictive segmentation approach will likely increase the number of event and control periods.

In conclusion this study has demonstrated that data collected using the Triage Changing Table may be useful in predicting impending hospital admissions. However, further research is needed to evaluate the true predictive potential of this tool.

Preliminary Evaluation of a mHealth Coaching Conversational Artificial Intelligence for the Self-Care Management of People with Sickle-Cell Disease

David-Z. ISSOM^{a,1}, Jessica ROCHAT^a, Gunnar HARTVIGSEN^b, Christian LOVIS^a

^a Division of Medical Information Sciences, Geneva University Hospitals, Switzerland

^b UiT The Arctic University of Norway, Tromsø, Norway.

Abstract. Adherence to the complex set of recommended self-care practices among people with Sickle-Cell Disease (SCD) positively impacts health outcomes. However, few patients possess the required skills (i.e. disease-specific knowledge, adequate levels of self-efficacy). Consequently, adherence rates remain low and only 1% of patients are empowered enough to master the self-care practices. Health coaching and therapeutic patient education have emerged as new approaches to enhance patients' self-management and support health behavior changes. This preliminary feasibility study examined patients' perceived usefulness of the information provided by a chatbot we developed following patient-important requirements collected during our preliminary studies. Participants tested the chatbot and completed a post-test survey. A total of 19 patients were enrolled and 2 withdrew. 15 respondents (15/17, 88%) gave a score of at least 3/4 to the question "The chatbot contains all the information I need". Results suggest that mHealth coaching apps could be used to promote the knowledge acquisition of recommended health behaviors related to the prevention of SCD main symptoms.

Keywords. Sickle-Cell Disease, Chatbots, mHealth, Patient Empowerment.

1. Introduction

Sickle-Cell Disease (SCD) is the most prevalent monogenic disorder worldwide [1,2]. The major clinical manifestations are hemolytic anemia and vaso-occlusive pain crises (VOC) [3]. Triggers of VOCs are numerous and include inadequate eating behaviors, stress, infections, dehydration, fatigue [4]. To prevent them, patients require high cognitive capabilities, good disease-specific knowledge and high self-efficacy levels [5]. Yet, literature suggests that only 1% of SCD patients are empowered enough to fully self-manage [6]. Mobile health (mHealth) apps, because of their relatively low cost and scalability, can offer a potential route to support SCD self-management. Studies have shown that Conversational Artificial Intelligence (AI) such as chatbots to encourage people with Diabetes' behavior changes, had a high acceptability and high user engagement [7]. To our knowledge, no work has been done to design such tools for the specific needs of people with SCD. This preliminary study aims at evaluating patients' perceived usefulness of the information provided by a fully automated coaching app designed to empower patients through the learning of recommended self-care practices.

¹Corresponding Author; E-mail: david.issom@unige.ch.

2. Methods

To be part of the study, applicants had to be diagnosed with SCD. Patients had to be at least 16 years old and be able to understand French. People who had been cured (e.g., bone marrow transplantation) were excluded. Finally participants had to possess a smartphone. Patients have been recruited through patient associations in Guadeloupe during the World Sickle-Cell Awareness Day. All participants gave informed consent before the evaluation and all responses were anonymous. The instrument has been developed following patient-important requirements collected during our previous work [8,9]. Participants tested the chatbot and completed a post-test, the 9-items usefulness scale for patient information material (USE) survey.

3. Results

19 patients participated to the test (9 females and 8 males). 17 completed the evaluation. 2 females withdrew because of problems with their smartphones. Patients were aged between 19 and 59 years old. 15 respondents (15/17, 88%) gave a score of at least 3/4 to the question “The chatbot contains all the information I need” for a total score of 54/68. 10 participants (10/17, 58%) gave a score of at least 3/4 to the question “The chatbot encouraged me to be more active in order to improve my condition”, for a total of 51/68.

4. Discussion

Results suggest that chatbots for health coaching can be used to promote the knowledge acquisition of recommended self-care practices related to the prevention of VOCs.

Preliminary Evaluation of Market Mechanism-Based Bed Allocation System

Shusuke HIRAGI^{1a,b}, Osamu SUGIYAMA^a, Jun HATANAKA^b, Shosuke OHTERA^{a,b},
Goshiro YAMAMOTO^a, Kazuya OKAMOTO^{a,b}, Masayuki NAMBU^a, and
Tomohiro KURODA^{a,b}

^a *Kyoto University Hospital, Kyoto, Japan*

^b *Department of Social Informatics, Graduate School of Informatics, Kyoto University,
Kyoto, Japan*

Abstract. Effective bed management is important for hospital management. Until now, bed allocation process is generally controlled by administrative staffs in centralized manner but it is not always effective. In the present study, we proposed and evaluated new method for bed allocation applying market mechanism via token. Evaluation was performed with newly-developed game-type simulation. Nurse managers as research participants played it and answered for survey. The result showed that the proposed method can be useful with appropriate operational design.

Keywords. Hospital Management, Bed Occupancy, Resource Allocation

1. Introduction

Effective bed allocation is important for hospital management [1], as bed capacity is central part of hospital's competency. Current bed allocations are generally executed by administrators with centralized manner, but such management tends to result in front-line staffs' decreased job satisfaction and even invokes their resignation [2]. Considering that healthcare is labor-intensive industry, current state can be seen as ineffective and we need improvement. Conventional discussion in economics has argued that centralized decision making such as collectivist society cannot be efficient comparing to decentralized, market mechanism-based society. We here propose a novel bed allocation system based on market mechanism in which physicians who needs beds "select" and "buy" "price-tagged" impatient beds from nurse managers through transactions with token. We implemented preliminary game-like computer simulation and performed evaluation of the system through survey to nurse managers.

2. Method

We regarded bed allocation process as transactions of nursing services between physicians and nursing staffs. In particular, wards offer prices of their nursing services for physicians planning patient admission, and physicians buy them considering prices and their preferences. By doing so, we expected improved bed allocation from the

¹ Corresponding Author, E-mail: hiragi.shusuke.4x@kyoto-u.ac.jp

viewpoint of hospital management. To evaluate the system, we developed web-based simulation game in which three players were required to act as nurse managers of a hospital using aforementioned bed allocation system. Players were asked to set prices for patients as nurse managers followed by computer agent acting as physician selected the cheapest ward. The game was set to end when the tenth cycle ended. Next, we recruited three nurse managers from a single university affiliated hospital in Japan. They were asked to play simulation game described above, assuming that they are carrying out their responsibilities as managers in the in-game world. As evaluation, we recorded price fluctuation and bed allocation results. In addition, we asked participants to answer several questionnaires.

3. Results

Research participants were nurse managers in active duty and all of them were female. Their work experiences were 20-34 years as nurse and 5-14 years as nurse manager. The prices of beds fluctuated according to wards bed occupancy. Answers of questionnaires were summarized as follows; participant A was generally skeptical to the system, while participant C was favorable. Even though their answers were diverse, they evaluated “patient-centeredness” of the system negatively while “fast decision making” neutrally or positively. When they were asked about preferred reward for collected tokens, they answered as follows: bonus, additional human resource, job training allowance, welfare expenses.

4. Discussion

In the present study, we proposed a new method for bed allocation and evaluated it with game-like simulation system. Simulation system showed slight association between bed occupancy and price for diseases, indicating nurse managers’ strategies considering surrounding situations. Referring conventional theories in economics, such rationalities of each stakeholders are expected to result in overall optimization [3]. In addition, participants showed their concern that the system could not be good for patient care because it does not reflect caregivers’ specialty. In addition, appropriate rewards for the tokens is said to be the key factor for the effective implementation for token economy [4]. Our survey also showed two of three participants preferred additional human resources. This result indicated that hospital administrators will be able to manage the system via controlling human resource allocations. In conclusion, token-based bed allocation system based on market mechanism approach can be effective when it is used with appropriate operational design.

Abstract. Our study team developed the MyPEEPS Mobile App for improving HIV prevention behaviors in diverse young men. We conducted a randomized controlled trial and evaluated the preliminary outcomes in the first half (N=350) of our intended study sample. Higher self-efficacy for HIV prevention behaviors ($p=0.0042$) and more recent HIV tests in the past 3 months ($p=0.0156$) were reported by the intervention group compared to control. Numbers of condomless anal sex acts were lower among the intervention group for both insertive anal sex acts ($p=0.0283$) and receptive anal sex acts ($p=0.0001$). Preliminary results indicate that some sexual risk behaviors were reduced among the intervention group in the preliminary analytic sample.

Keywords. mHealth, digital personalized health, young men, HIV prevention

1. Introduction

Increased HIV incidence continues among young men who have sex with men (YMSM), with rates especially disproportionate among racial and ethnic minority YMSM in the US. Yet, there remains a dearth of evidence-based HIV prevention interventions for YMSM – and few that address racially- and ethnically-diverse YMSM. We employed a community-engaged research approach to design the MyPEEPS Mobile App targeting ethnically-diverse YMSM. MyPEEPS delivers information through 21 activities comprised of: didactic content, graphical reports, videos, and true/false and multiple-choice quizzes. [1] This ongoing randomized controlled trial is testing the efficacy of MyPEEPS, an evidence-based intervention for

¹ Corresponding Author: E-mail: rb897@columbia.edu.

reducing sexual risk behaviors (e.g., sex without condoms) and strengthen protective factors (e.g., increasing self-efficacy around safer sex) among racially and ethnically diverse YMSM across the US.

2. Methods

Young males (ages 13-18) who report same-sex attraction and have kissed another male or plan to have sexual activity with another male in the next year were recruited from across the US (Figure 1). Enrolled participants provide demographic, psychosocial, and sexual behavior data at baseline. The intervention group receives the MyPEEPS Mobile App at the baseline visit, with follow-up assessments at 3-month, 6-month, and 9-month time points. The control (delayed intervention) group completes 3-month, 6-month, 9-month, and 12-month assessments. Regression analyses assessed data collected from a sub-sample of 350 baseline visits and 271 matched 3-month visits.

Figure 1. MyPEEPS Mobile social media recruitment banner.

3. Results

Higher self-efficacy for HIV prevention behaviors ($p=0.0042$) and more HIV testing in the past 3 months ($p=0.0156$) were reported by the intervention group compared to control. Numbers of condomless anal sex acts were lower among the intervention group than control for both insertive anal sex acts ($p=0.0283$) and receptive anal sex acts ($p=0.0001$). The intervention group reported fewer condomless insertive anal sex acts ($p=0.0061$) but more condomless receptive anal sex acts than the control group ($p=0.0001$) while under the influence of alcohol and drugs. There were no group differences in the other HIV prevention measures.

4. Conclusions

Preliminary results indicate that some sexual risk behaviors were reduced among the intervention group in the preliminary analytic sample. Further analysis after study completion will provide more conclusive results.

Preliminary Safety Analysis of a Wearable Clinic for the Early Detection of Psychotic Relapse

Ibrahim HABLI^{a,1}, Charlotte STOCKTON-POWDRELL^b, Matthew MACHIN^b, Paolo FRACCARO^b, Shon LEWIS^b and Niels PEEK^b

^aUniversity of York, United Kingdom

^bUniversity of Manchester, United Kingdom

Abstract. We discuss the preliminary safety analysis of a smartphone-based intervention for early detection of psychotic relapse. We briefly describe how we identified patient safety hazards associated with the system and how measures were defined to mitigate these hazards.

Keywords. Safety, wearables, smartphones apps, serious mental illness

1. Introduction

We focus on a smartphone-based intervention, called the Wearable Clinic, which assists in remote monitoring of patients with chronic conditions, including serious mental illness. A key function of the Wearable Clinic is to detect relapse early by identifying sudden changes in activity and behaviour, particularly for patients with schizophrenia. Relapses often result in unscheduled hospital admissions, with substantial suffering of affected individuals and their families as well as high costs for mental health services. Despite the potential benefits of the Wearable Clinic, it is a complex digital intervention in a complex clinical and social setting. This increases the risk of new unintended hazardous events that can compromise patient safety [1]. The aim of this paper is to show how the consideration of these safety concerns was incorporated into the early design of the Wearable Clinic by proactively conducting a hazard analysis in order to generate safety requirements for mitigation of the identified safety hazards.

2. Methods

We modelled the intended use of the Wearable Clinic for an early detection of psychotic relapse in an explicit use case, clearly representing the flow of activities, decisions and data. This activity has been conducted with a multidisciplinary team comprising data scientists, engineers, economists, clinicians and public contributors. This use case provided a basis for scoping and conducting a hazard and risk analysis, which is a mandatory requirement for safety standards. The safety analysis of the

¹ Corresponding Author, Ibrahim.habli@york.ac.uk.

Wearable Clinic, as scoped by our use case, was conducted using the Software Hazard Analysis and Resolution in Design (SHARD) technique [2]. SHARD is used in the safety-critical domain to assess the suitability of a proposed design of a data-intensive system and derive safety requirements for the detailed development of the design. SHARD is structured around data flows, considering inputs to the system, e.g. from sensors, and outputs, e.g. to alerting devices. SHARD uses a set of guide words (*omission*, *commission*, *early*, *late* and *value*) for identifying potential deviations from the intended behaviour of each data flow, prompting the analysts to determine plausible causes, hazardous effects and the safety requirements.

3. Results

SHARD was applied to all the data flows in the use case. Take the data flow between the decision ‘*Is risk of relapse high?*’ and the activity ‘*Inform care team*’, considering three key deviations (*omission*, *commission* and *late*). Here, the omission and late reporting of high risks of relapse represent two potential hazardous failures that have to be mitigated. For example, a potential omission cause is a common smartphone notification option that can centrally disable all notifications. This could limit the ability of the Wearable Clinic to collect user data and thus to proactively predict relapse. A mitigation measure comprises user training and greater control over central OS functions. These form explicit safety requirements for the subsequent detailed design, and the potential deployment, of the app.

4. Discussion and Conclusions

An important feature of the Wearable Clinic is that its functions are interweaved into the care pathway. With this benefit comes the challenge of identifying the safety considerations that have to be mitigated specifically by the Wearable Clinic designers. For example, is the scope of the system limited to (1) alerting the care team, (2) automatically initiating an intervention or/and (3) guiding the intervention? The greater the scope, the more safety-critical the system becomes, with more stringent regulatory constraints. Further, the confidence with which the safety requirements have to be satisfied should be proportionate to the risks posed by the technology. However, neither the safety standards nor clinical guidelines state what would be deemed as acceptable risk targets. Without these targets, it is a significant challenge for the engineers to make transparent decisions concerning the reliability of the different system components, e.g. choice of accelerometers or mobile phone platforms, in the absence of any qualitative or quantitative notion of risk acceptance.

^dNuffield Department of Primary Care Health Sciences, University of Oxford, UK

Abstract: Although routine healthcare data are not collected for research, they are increasingly used in epidemiology and are key real-world evidence for improving healthcare. This study presents a method to identify prostate cancer cases from a large English primary care database. 19,619 (1.3%) men had a code for prostate cancer diagnosis. Codes for medium and high Gleason grading enabled identification of additional 94 (0.5%) cases. Many studies do not report codes used to identify patients, and if published, the lists of codes differ from study to study. This can lead to poor research reproducibility and hinder validation. This work demonstrates that carefully developed comprehensive lists of clinical codes can be used to identify prostate cancer; and that approaches that do not solely rely on clinical codes such as ontologies or data linkage should also be considered.

Keywords. Prostate cancer, primary care, case identification, real-world evidence

1. Introduction

Prostate cancer is a chronic condition, with good prognosis but long-term consequences. Health services worldwide are stretched so it is important to understand the needs of the growing population of people affected by cancer. The increasing use of electronic health records (EHRs) can facilitate epidemiological research. However, the usability of data is limited by the lack of standards and variability in the quality of recording of cancer diagnosis and treatment. In this study, we investigate the usability of clinical codes to identify and describe a cohort of prostate cancer patients from an English database.

2. Methods

A primary care-based, retrospective cohort study using a nationally representative, English database from the Royal College of General Practitioners (RCGP), Research and Surveillance Centre (RSC) was used [1]. A December 2016 data extract was analyzed comprising 164 practices and 1,529,922 EHRs for male patients.

¹Corresponding Author, E-mail: agnieszka.lemanska@npl.co.uk

Prostate cancer diagnosis was extracted using commonly reported diagnostic codes. This included B46 (*malignant neoplasm of prostate*), B834 (*carcinoma in situ of prostate*) and HNG0200 (*cancer of the prostate*). We also included 4M01 and Xalmc (*Gleason prostate grade 5-7 (medium)*), and 4M02 and Xalmd (*Gleason prostate grade 8-10 (high)*). Date and age at diagnosis was based on the first occurrence of the clinical code. Ethnicity was extracted in five categories using an ontology-based algorithm [2].

3. Results

The average age at diagnosis was 70.8 (SD = 9.5) and the majority of men (11,586, 94.1%) were white (Table 1). Men identified with prostate cancer were spread evenly across the country (Figure 1). The most commonly extracted treatment was hormone therapy, 9324 (47.5%) men received it. The mean age at death was 80.6 (SD = 9.1).

Diagnosis was established for 19,619 (1.3%) men. The three codes: B46, B834 and HNG0200 were used for 18,356 (93.6%), 1,549 (7.9%) and 666 (3.4%) men respectively. Medium Gleason grading was recorded in 1535 EHRs and high in 562 EHRs. This enabled identification of 94 (0.5%) additional cases.

Characteristic	Mean (SD)	n (%)
Age at diagnosis (years)	70.8 (9.5)	
Ethnicity		
White		11586 (59.1)
Asian		195 (1.0)
Black		432 (2.2)
Mixed		67 (0.3)
Other		37 (0.2)
Missing		7302 (37.2)
Treatment		
Radiotherapy		634 (3.2)
Hormone therapy		9324 (47.5)
RT and HT		1970 (10.0)
None recorded		7691 (39.2)
Age at death (years)	80.6 (9.1)	
Not recorded		18170 (92.6)

Table 1. Demographic and treatment characteristics

Figure 1. Location of study participants.

4. Discussion and conclusion

Primary care-based epidemiological studies often identify cancer cases using diagnostic codes. In clinical practice, we found variations in the recording of cancer diagnosis. This work contributes to establishing standards for primary care cancer case ascertainment.

Proposal of an Architecture for Terminology Management in a Research Project

Sara MORA^{a,1}, Sumit MADAN^b, Stephan GEBEL^b, Mauro GIACOMINI^a

^a*Department of Informatics, Bioengineering, Robotics and System Engineering (DIBRIS), University of Genoa, Italy*

^b*Fraunhofer Institute for Algorithms and Scientific Computing SCAI Department of Bioinformatics Schloss Birlinghoven, Sankt Augustin, Germany*

Abstract. Clinical and medical knowledge evolve and this causes changes in concepts and terms that describe them. The objective of this work is to formally present an ontology-based standard architecture that will be used in the scenario of neurodegeneration research to maintain terminologies and their relations updated and coherent over the time. The proposed structure is composed by three elements that will allow the user to do a list of operations on the terminology resources explicitly contemplated by the *Common Terminology Service Release 2* (CTS2).

Keywords. CTS2, ontologies harmonization.

1. Introduction

As in all scientific domains, clinical and medical knowledge evolve over time. In a scenario of multiscale and multimodal data integration it is mandatory to use shared semantics because of the need to deal with heterogeneous datasets [1]. In order to correctly manage this type of semantic framework, it is important to consider that the medical knowledge evolution causes the change of concepts and of the terms used to define them. For this reason, it is necessary to manage historical evolution and versioning [2]. So, in the scenario of collaboration projects, it is essential to use both controlled vocabularies and standard infrastructures to guarantee both high-quality data collection and interoperability between partners.

2. Methods

As defined in [3], ontologies have been originally developed from the need to represent and to communicate a domain's knowledge unambiguously. As the project is linked to neurodegeneration research, a group of specific ontologies have been selected. This will not only guarantee the correct dialogue between homogeneous datasets, but it will also support the information extraction workflows for “cause-and-effect”-type relationships. Ontologies are not isolated; indeed, it is possible to define links between them in a process of ontologies harmonization. The four ways to reach this goal are: matching, mapping, alignment and merging. In the context of this work, it will be

¹ Corresponding Author, E-mail: sara.mora@edu.unige.it

necessary to guarantee the correct mapping between the ontologies. As detailed in [4], the objective of CTS2 is to provide technical and functional specifications for the development of service interfaces based on the *Service Oriented Architecture* (SOA) that allow the management, search and reading of terminological content defined both locally and internationally. The CTS2 standard provides a list of terminology resources and, for each of them, a list of functional profiles has been defined.

3. Results

The proposed architecture is composed by three elements: a relational database, where all the ontologies and information about them will be stored (already developed and not part of this project); a CTS2 compliant Windows Communication Foundation (WCF) service whose interface exposes all the operation contracts expected by the CTS2 standard (already developed and not part of this project); a CTS2 compliant web application, client of the WCF service. This web platform will give the user the possibility to easily use the functionalities of the CTS2 compliant Service, for example: create, update, delete a terminology resource; read a terminology resource in a specific context; search the terminology resources with specific features in a certain context and get the list of all the changes applied to a particular terminology resource. Moreover, the use of controlled vocabularies, defined in different countries, will help the data extraction and integration from different sources containing notes, reports and referrals written in the original languages of the countries involved in the present project.

4. Discussion & Conclusions

The proposed architecture allows the correct management of mappings between different ontologies over the time and to monitor the evolution of a terminology resource through different versions. Future works will be the development of the web application cited above and the possibility of using a non-SQL database instead of a relational one.

Providing Personal Health Records Based on a Mobile Application for Emergencies

Su Min KIM^a, Suyoung YOO^a, Won Chul CHA^{a,b}, Tae Rim KIM^{a,b}

^a*Samsung Advanced Institute for Health Science & Technology (SAIHST),*

Sungkyunkwan University, Seoul

^b*Samsung Medical Center, Seoul*

Abstract. We developed the service showing patient health record altogether which is managed by each hospital separately and recording the patient health information based on mobile application. We evaluated the effectiveness and satisfaction of the service. This study is aimed to reduce instances where patient's medical records are unknown to the medical staff in emergencies and allow patients to use and utilize their health information.

Keywords. Personal medical information, personal health report, mobile application, emergency

1. Introduction

With the aging and increase of chronic diseases, the importance of continuous health care is increasing. In addition, there has been an increasing demand for patients to manage and use their own medical information previously held by medical institutions. However, there was a limit to developing an appropriate platform between information providers and consumers. The purpose of this study is to develop appropriate channels for returning sovereignty of medical information to patients.

2. Method

The three hospitals, including Samsung Medical Center, provided application-based services for emergency patients called Firster to 1,000 emergency patients or carers and 12 medical staffs. Patients and carers are surveyed on the usability and satisfaction and the System Usability Test (SUS). Set a target of 69.5, which is slightly above the 68 SUS score that 50% of people in the reference evaluate, a total sample size of 1,000 was obtained based on one sample and t test.

Afterwards, interviews to Patients, carers and medical staffs are conducted to further explore usability and satisfaction.

3. Results

This study was conducted from October to November 2019 and the data is analyzing, thus this paper included only a few results of the data analysis. A total of 1,000 patients or carers participated in the demonstration, and the average of system usability test (SUS) was 67.08 (SD=13.8), which was lower than the average of 68 as the reference.

However, The lower the age, the higher the usability and satisfaction.

As a result of dividing into two groups based on the average SUS score of 68, the age group under 56 showed a high rate in the group with over SUS 68. As a result of comparing the usability of the smartphone and the usability of the app, the group with over SUS 68 showed higher usability than the group with under SUS 68.

Table 1 Comparison between two groups by SUS score under and over 68

	Total (N=1,000,100%)				Under SUS score 68 (N=560, 56.0%)		Over SUS score 68 (N=440, 44.0%)	
	age	n	%	SUS	n	%	n	%
	19~35	374	37.4	69.6(12.3)	178	31.8	196	44.5
	36~55	452	45.2	68.0(13.9)	252	45.0	200	45.5
	Over 56	174	17.4	59.5(14.7)	130	23.2	44	10.0
					mean		mean	p-value
Smartphone usability*					3.96(sd=0.61)		4.2(sd=0.46)	<0.05
SUS*					57.6(sd=9.82)		79.1(sd=7.40)	<0.05

* Smartphone usability: 5 score is the highest

4. Discussion and conclusion

The average of SUS was 67.08 (SD=13.8), which was lower than the average of 68 as the reference. But the period for demonstration was just 2 months and it was conducted only three hospitals. Therefore, we cannot predict the service usability and satisfaction of this service because it is still in the process of proof. Through demonstration, the usability of the app service varies with age and smartphone using status; The older people tend to have lower usability than the younger people do. There should be efforts to improve the usability of the high-age population.

It is expected that the personal health information utilization service will improve access to health information that has been managed separately by each medical institution and facilitate the utilization of health information, thereby reducing emergency difficulties and responding to the needs of patients for health information.

Qualitative Study to Design an Online Community for Patients with Psoriasis

Giuliana COLUSSI^{1a}, Janine SOMMER^a, Mariana SIMÓN^a, Lucila BRUCHANSKI^a,
Daniel LUNA^a

^a Health Informatics Department, Hospital Italiano de Buenos Aires, Argentina

Abstract. The aim of this research was to understand the needs of patients with psoriasis and the concerns of specialists in this pathology. Interviews with adults with psoriasis and dermatologists were conducted. We found 4 main dimensions: Frequently asked questions; Social stigma; Education to patients and Patient empowerment. The findings represent a first approach to understand the needs and perceptions of patients and dermatologists, for the design of a virtual community.

Keywords. Self-Help Groups, personal health records, psoriasis

1. Introduction

A virtual community in healthcare refers to a group of people who interact with each other, performing activities related to healthcare and education [1]. Patients with a recent diagnosis in which doubts and fear may arise, could find in virtual communities psychological support [2] by contacting people who have gone through similar circumstances. Participation of patients with long-term health conditions as psoriasis, improves self-control of the disease, produces positive outcomes related to health [3], facilitates shared decision making [4] and can even reduce mortality [5]. The objective of this research was to understand the needs of patients with psoriasis and the concerns of specialists in this pathology; for the design of a virtual community of patients with psoriasis into our PHR, applying user-centered design techniques.

2. Methods

We conducted a qualitative study, based on in-depth, semi-structured individual interviews to both patients and physicians. Patient selection was based on a convenience sample of adult patients diagnosed with psoriasis, whereas for physicians selection, we included dermatologists specialized in this disease. Each interview was audio-recorded, with the prior informed consent and protecting participants' confidentiality. We proceeded to analyze and categorize the information in domains according to the main findings. The analysis was performed through codification and categorization of the information, based on a process of constant comparison [6].

¹ Corresponding Author: E-mail: giuliana.colussi@hospitalitaliano.org.ar.

3. Results

We conducted 15 interviews with patients and 9 with dermatologists. We found 4 main dimensions. 1) *Frequently asked questions*: Patients were frequently interested on finding out causes of their disease, types of treatments available and treatment options that have shown better results. 2) *Social stigma*: Beyond the typical physical signs of the disease, the major source of patient discomfort came from social stigma and discrimination. An informed patient, might be beneficial for the community by promoting the dissemination of information on the the non-contagious status of the disease and thus, helping to overcome barriers in terms of social stigma. 3) *Patient Education*: Most patients will have read information on the internet, by the time they arrived to the physician appointment. Dermatologists argued about the difficulties they face trying to change patients minds once they have already acquired false beliefs and knowledge. 4) *Patient empowerment*: Most participants mentioned that it would be interesting to include questionnaires about the longitudinal follow-up of this pathology. and it would be interesting for patients to self-report these questionnaires in order to have a complete follow-up. Besides, it could represent a benefit for doctor-patient relationship since the time they now-a-days expend completing these questionnaires during the office visit, could be used to address other important topics.

4. Discussion

The main findings obtained from the interviews were related to information and education needs along with recommendations regarding psoriasis management, as well as the physical, emotional and social impact generated on people and the approach from the patient and family perspective [7].

We detected the need of a technological tool capable to give patients access to reliable information sources, promote online information sharing with the medical team or peers, and facilitate data management according to users experience [7]. The main findings will help us to develop a tool focused on user needs. Conclusively, this research represents the first step in the design of a virtual community by understanding the needs and perceptions of patients and dermatologists.

^aMinistry of Health, Argentina

^bMinistry of Modernisation, Argentina

Abstract. The Ministry of Health (MoH) set the National Digital Health Strategy 2018-2024 as a state policy. It included a National TeleHealth Plan to enhance access and quality of healthcare in a wide territory like Argentina, leveraging more than 20 years of national telemedicine experiences and coordinating it with the territorial integrated health service networks proposed by the Universal Health Coverage strategy. In collaboration with the Ministry of Modernisation, the MoH developed and implemented a new TeleHealth Web Platform to perform eReferrals and eConsultations nationwide. This poster describes the first 2 months of usage.

Keywords. Telehealth, eConsult, eHealth, Telemedicine.

1. Introduction

Digital Health is one of the three pillars for the effective implementation of Universal Health Coverage in Argentina. The Ministry of Health (MoH) created a National Directorate of Health Information System to coordinate the National Digital Health Strategy 2018-2024. It included a National TeleHealth Plan to promote the development of this technology.

In collaboration with the Ministry of Modernisation, the MoH developed and implemented a new TeleHealth Web Platform to perform eReferrals and eConsultations nationwide. The teleconsultation platform allows primary care physicians located in remote areas to contact specialist for difficult patient cases[1], improving communication, and eventually avoiding physical referral. It was designed to close territorial specialist availability gaps[2]. In-advance training and education for leaders and end-users is one of the critical factors[3]. Governance and management aspects of Telemedicine are crucial, and have the potential of transformative challenge for the health system [4]. The platform was developed using international standards suggested by the MoH. The components were: the front end; a layer of data services; a back end that is responsible for persisting and retrieving information and a server to store the database. We used Fast Healthcare Interoperability Resources (FHIR), such as service request. This poster explains the first overview of its implementation.

2. Materials and Methods

The analysis of the implementation was done using de-identified data exported from the system, regarding institutions, specialties, telemedicine programs and teleconsultations.

3. Results

The Platform implementation was rolled out in 2 phases: an initial pilot with 2 provinces and a big bang adoption in the whole country afterwards. Previously, main leaders took a telehealth course provided by Mina Gerais University. Final users were trained locally. Explanatory videos and manuals were available through the MoH website. Initial parameterization, helpdesk and support was in charge of MoH personnel. Telemedicine Programs were created based on specialties and health disorders coded with SNOMED. Each province created healthcare institution networks, called Subsystems, and set the rules for the teleconsultations workflow. Interestingly, 23 out of 24 (95.8%) provinces started using the teleconsultation platform.

During the first 2 months, 18 telemedicine programs were created. The most used were Tele-Pediatrics (TPed) and Tele-Internal Medicine (TIM). The TPed program is well consolidated, based on a longstanding experience since 1987. Even though in August 2019 the consultations were 87.14% for TPed and 12.86% for TIM, in September the adult program usage increased 146%: 81.1% (TPed); 18.6% (TIM).

Regarding the reason for teleconsultation, 31.8% were initiated to reach a diagnosis, 20.4% were looking for treatment advice, 18% for physical referral request. Few consultations asked for an interventional procedure (11.3%), while 10.93% needed further lab or image studies. Finally, other categories were counter-reference (7.03%), prevention (0.35%) and rehabilitation (0.18%).

4. Conclusion

The TeleHealth Web Platform for eConsultations is a promising tool to close accessibility gaps and enhance territorial integrated health service networks.

Risk Factors for Chronic Diabetes Patients

Oleg METZKER^a, Kirill MAGOEV^a, Stanislav YANISHEVSKIY^b, Alexey YAKOVLEV^b and Georgy KOPANITSA^a

^a*ITMO University, Saint Petersburg, Russia*

^b*Almazov National Medical Research Centre, Saint Petersburg, Russia*

Abstract. Specific predictive models for diabetes polyneuropathy based on screening methods, for example Nerve conduction studies (NCS), can reach up to AUC 65.8 – 84.7 % for the conditional diagnosis of DPN in primary care. Prediction methods that utilize data from personal health records deal with large non-specific datasets with different prediction methods. It was demonstrated that the machine learning methods allow to achieve up to 0.7982 precision, 0.8152 recall, 0.8064 f1-score, 0.8261 accuracy, and 0.8988 AUC using the neural network classifier.

1. Introduction

Every third patient with diabetes suffers from diabetic polyneuropathy (DPN). This complication is a severe problem for a chronic patient because it can be accompanied by neuropathic pain and lead to a decrease in the quality of life. Neuropathic pain significantly disrupts sleep, negatively affects daily activity and life satisfaction. The earlier the diagnosis is found, the easier the disease can be managed. Several studies on the prediction of diabetes mellitus that utilize Linear regression (LR) developed predictive models based on records with up to 967 independent variables available from large electronic health record archives resulted in up to 0.80% Area Under The Curve Receiver Operating Characteristics (AUC-ROC) and enabling to formulate the most likely trajectory of comorbidities. Application of the ensemble models approach based on the naïve Bayes, Linear regression (LR), Instance-Based Learner, support vector machine (SVM), artificial neural networks (ANN), decision trees, and random forest (RF) help to increase the accuracy of diabetes prediction with the accuracy of up to 74%. The goal of this study is the implementation of machine learning methods for early risk identification of diabetes polyneuropathy based on structured electronic medical records.

2. Methods

The dataset contains a total number of 238590 laboratory records. Each record contains patient and episode identifiers, a timestamp, and a varying number of measured parameters, the total number of which is 31 (27 laboratory tests, retinopathy, nephropathy, age, and gender). The records include information 5846 diabetic patients. Diagnosis served as the source of information about the target class values. To identify subclasses within the class of patients with diabetes, the classification problem was solved. Each experiment ran in the setting of stratified 5-fold cross-validation (i.e., random 80% of patients were used for training and 20% for testing, target class ratios in

the folds were preserved). The AUC was calculated based on an average of 5 curves (one curve per fold in the setting of 5-fold cross-validation).

3. Results

There are two large clusters (#0 and #3) that are opposite to the percentage of patients with polyneuropathy, namely the smallest and the largest rate of polyneuropathy. Cluster # 0 has an increased rate of patients with polyneuropathy: 59 %. In cluster #3, on the contrary, the reduced number of patients with polyneuropathy is 22 %. However, these are both female clusters. In male clusters #1 and #2, the percentage is close to the average. Cluster #4 is slightly below average. In clusters 0, 1, and 2, patients are about the same age. The difference in cluster 1 is that there is an outlier on the left, and it is male in contrast to cluster 0. Cluster 3 patients are young men, younger than patients cluster 0, 1, and 2, and also male. Cluster 4 are young male patients, which explains their low percentage of polyneuropathy. Cluster 5 patients of different ages with a small portion of polyneuropathy are mostly men. It is evident that the female gender and the age of more than 50 years is a risk factor for the development of polyneuropathy in patients with diabetes mellitus. However, there is a particular group of young men (cluster 4) with the probability of polyneuropathy. As a result of the cluster analysis, several groups of patients were identified: younger men and women (clusters 4 and 3, the share of polyneuropathy is significantly lower), older men and women (clusters 1 and 2: men, 0: women, the share of polyneuropathy is significantly higher). The most significant features were those of neutrophils and glucose level in the blood and the urine. The correlation matrix shows the high correlation of MPW, RBC, HGB, and polyneuropathy. If we discuss the main features (indicators) affecting the development of polyneuropathy in diabetes, the presence of a decrease in the relative number of segmented neutrophils, which supports the postulate of the main contribution of monocyte cells in the process of inflammation development [13], as well as signs of unsatisfactory glycemic control manifested in glucoseuria and hyperglycemia, become clinically important events.

4. Discussion and conclusion

Clustering shows differences within patients with diabetes mellitus. Decision trees demonstrate pathophysiological mechanisms. It was demonstrated that inclusion of just two features, namely “nephropathy” and “retinopathy”, allows to increase the performance even further, achieving up to 0.7982 precision, 0.8152 recall, 0.8064 f1-score, 0.8261 accuracy, and 0.8988 AUC using the neural network classifier.

Rosacea Patients Are at Higher Risk for Obstructive Sleep Apnea: Automated Retrospective Research

Peter L. ELKIN^{1,2}, Sarah MULLIN^{1,2}, Sylvester SAKILAY^{1,2}

¹*Department of Biomedical Informatics, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, SUNY, USA*

²*Western NY VA, Department of Veterans Affairs*

Abstract. Using big data science we employ NLP and a novel interface the BMI Investigator to answer clinically meaningful questions. The use case presented is the association between Rosacea and Obstructive Sleep Apnea.

Keywords. Big data science, information Retrieval, NLP, Rosacea, Obstructive Sleep Apnea

1. Introduction

Automated retrospective research is a goal of an EHR driven research program. Here with this application we can go from clinical observation to science in ten minutes using a large cohort driven observational database linked to codified clinical notes using SNOMED CT. In this study we show that patients with Rosacea are at significantly increased risk for Obstructive Sleep Apnea (OSA).

Rosacea is a chronic skin condition that typically affects the face.[2][3] It results in redness, pimples, swelling, and small and superficial dilated blood vessels.[2] Obstructive sleep apnea (OSA) is the most common type of sleep apnea and is characterized by repeated episodes of complete or partial obstructions of the upper airway during sleep, OSA is usually associated with a reduction in blood oxygen saturation.

The BMI Investigator is a computer human interface built in .Net which allows simultaneous query of structured data such as demographics, administrative codes, medications (coded in RxNorm), laboratory test results (coded in LOINC) and formerly unstructured data in clinical notes (coded in SNOMED CT). The SNOMED CT codes are stored using Berkley DB and NoSQL Elastic Search, and the structured data is stored in SQL using the OMOP / OHDSI format. We have integrated genomic data into the software platform and are working to integrate image features into the query engine.

2. Methods

We use the high throughput phenotyping – Natural Language Processor (HTP-NLP) developed at the University at Buffalo.[4]. The BMI Investigator application was written in .Net and was created using the user-centered design development method with a team of programmers, physicians, graduate students and faculty [5,6]. We tested the system on

a population of 212,343 patients in our outpatient practices at the UBMD practice plans age 18 and older. The data for this trial was from 2010 to 2015. The data used in the system was judged by the IRB to be IRB Exempt #587570. The system allows users to use Boolean logic and parentheses to construct their queries.

Genomic data is presented as gene abnormalities that are used in clinical medicine and polymorphisms that have been identified are stored in a separate set of tables and they are also used to match to our patients who are included in the precision oncology project [7]. In an exploratory analysis, which took five to ten minute, we entered four queries into the BMI Investigator (Rosacea, Rosacea and OSA, OSA, total eligible cases in the database) and used a Pearson Chi-Square test to compare the results.

3. Results

The dataset has 212,343 patients. 211,764 patients did not have Rosacea. 5443 patients had OSA without Rosacea. 580 patients had OSA with Rosacea and 51 patients had OSA with Rosacea. The chance of OSA without Rosacea was 5443/211,764 (2.6%). The chance of OSA with Rosacea was 51/580 (8.8%). The Pearson Chi-Square test showed a p-value of <0.001. The relative risk of OSA given Rosacea was 3.4 times those patients without Rosacea. The number needed to test was only 12 to get one positive case.

4. Conclusions

The BMI investigator is an evolving tool linked to observational EHR data that has the ability to facilitate rapid retrospective research which can be clinically relevant. In this case we have shown evidence that patients with Rosacea are at increased risk for Obstructive Sleep Apnea and with a low number needed to test (NNT) they should all be asked the screening questions for OSA and if positive they should be considered for polysomnography (a sleep study). Many more studies and quality and safety projects are possible using the EHR based data and the BMI Investigators.

Safety and Drugs: How Do We Record Medication Consumption and Prescription in Electronic Medical Records? A Look on Aspirin

Mercedes VOLPI^{a,1}, Santiago ESTEBAN^a and Sergio TERRASA^a

^a*Family and Community Medicine Division, Hospital Italiano,
Buenos Aires, Argentina*

Abstract. Background: documentation of aspirin consumption is usually not complete and clear, probably because it's a cheap drug that can be easily acquired. Objective: To evaluate the quality of the record of aspirin consumption documented in the electronic medical records (EMRs) of a Private University Hospital of Argentina. Design: Qualitative and quantitative descriptive exploratory study. Results: principal findings were that 86 % of the notes mentioned aspirin as a chronic prescription. 12% mentioned its temporary suspension. Numerous EMRs mentioned the use of an "antiplatelet" drug without specifying which, and didn't specify abbreviations, consumed dose or when to start or stop aspirin. Conclusions: overall quality of aspirin related information registration in EMRs was poor. This is concerning since it's a frequently prescribed drug, not exempt from adverse events.

Keywords. Aspirin, record, EMR, consumption

1. Background

Although medication consumption is the first cause of adverse events [1][2], information about drugs taken by patients is often not documented in electronic medical records (EMRs). For example, aspirin consumption (dosage, initiation or suspension) is not usually complete and clear, probably because it's a cheap drug that can be easily acquired over-the-counter.

2. Objective

To evaluate the quality of aspirin related consumption information documented in the EMR of a Private University Hospital of the Metropolitan Area of Buenos Aires, Argentina.

3. Design

We developed a keyword-based filter using expert knowledge, that allowed us to detect clinical notes in which aspirin was mentioned. We tested it on a manually annotated

¹ Corresponding author E-mail: mercedes.volpi@hospitalitaliano.org.ar.

sample of 2000 clinical notes, obtaining a sensitivity of 100% (95% CI 82.3 - 100) and a specificity of 100% (99.6 - 100). Using the filter, we obtained a sample of 1752 clinical notes which contained at least one of the keywords. These notes were manually reviewed and classified according to the information on aspirin consumption that they contained in the following categories: *current, chronic or temporary consumption of aspirin, definitive or temporary suspension, and indication to start it permanently or temporarily*. We also performed a qualitative description of how professionals document its use.

4. Results

86% (95% CI 84.2 - 87.6) of the notes referred to the current use of aspirin as a chronic prescription, 12% (10.5 - 13.6) mentioned its temporary suspension, 6.9% (5.7 - 8.2) mentioned the indication of starting it daily, 1.4% (0.91 to 2.1) referred to a temporary initiation and 1.2% (0.7 to 1.8) a permanent suspension. Numerous records did not clarify the dose the patient consumed or when they should start or stop taking it. We noted abbreviations of aspirin (i.e. omission of letters) that had not been clarified previously and many records mentioned the use of an "antiplatelet" drug without specifying it.

5. Discussion

Registration errors were more severe in notes describing changes of aspirin use. We did not review the structured systems that document the use of drugs in EMR. We only focused on unstructured clinical notes where health professionals often write changes in pharmacological treatments. We wonder what would be the closest to an ideal model of medication reconciliation and if a single health record compatible with the different levels of care would be possible.

6. Conclusions

Although there is consensus that having a complete pharmacotherapeutic history of patients optimizes health decision-making, we found a poor quality of registration of an accessible and inexpensive drug such as aspirin, which is not exempt from adverse events and whose chronic use is frequent.

Service Personalization in IT-Supported Finnish Healthcare

Olli KORHONEN^{a,1}, Vasiliki MYLONOPOULOU^b, and Guido GIUNTI^a

^aUniversity of Oulu

^bUniversity of Gothenburg

Abstract. This paper reports a case study on the spontaneous personalization discussions emerged from interviews with healthcare professionals when asked about their work practices and the role of information technology (IT) during consultations. We thematically analyzed the personalization elements using an existing personalization framework to provide insights on the service personalization. Our results contribute to the better design of IT solutions that can support health services' personalization.

Keywords. Personalization, Healthcare, Service Design, Case Study

1. Introduction

As the Healthcare User's (HU) characteristics, medical condition, and personal preferences vary, they should be treated individually making Health Service personalization (HSP) important. HS often take place between the healthcare professional (HP) and HU, supported by IT [7]. IT can act as facilitator for HSP, providing data about HU's particular characteristics [2] to be used by HP and HS during HS delivery [5,7]. In service design, the users and their context are at its core [1]. This paper provides insights to the personalization field from a service design perspective [4] by presenting personalization elements, emerged by the analysis of an interview study [6] with a personalization framework [5].

2. Methods

We conducted 60 min semi-structured interviews with 6 HP working for more than 10 years in different levels in the Finnish primary care on behavioral change. It was a convenience sample of 1 nurse, 2 medical doctors, and 3 nutritionists. They described their practices, and the IT support in HS. The interview guide had 3 areas: HP background, work practices, and IT use. The guide did not include personalization-related questions. Authors independently thematically analyzed and later discussed the data related to personalization. To interpret our results, we used a personalization framework [5] related to the automation level IT provides for service personalization.

¹Corresponding Author, E-mail: olli.korhonen@oulu.fi.

3. Results

Coercive personalization refers to predetermined regulations influencing the HS personalization e.g. different IT-solutions offered in Finnish primary healthcare. Within the interviews, HP referred to the coercive personalization elements implicitly as the support systems and restrictions that were placed on their daily work.

Data display personalization refers to IT enabled personalized data for the stakeholders to interpret and make personalization related decisions. The HP used digital and none-digital types of data display support to illustrate cases of optimal behavior (e.g. a good meal portion image) which they discuss with the HU in comparison to their data. Data display support used also for progress monitoring during the behavioral change. The HU's (digital or paper-based) diary inputs lead to constructive discussions during consultation, helping HP to better understand and support their HU.

Collaboration-based personalization refers to IT supported personalization between stakeholders, HP and HU. In this case, it was mainly generated verbally during the consultation but counted with the support by technologies. HP and HU discussed to provide information and create understanding on HU's current and past behavior, context, life situation, motivation, and social circle.

4. Discussion & Conclusion

The need for personalized solutions is frequently presented in the literature [3]. We applied the service design approach in healthcare setting, which is uncommon [4] as quantitative approaches are more valued than qualitative [8]. The use of a personalization framework [5] resulted in a better understanding of the HP views, which may help improve IT solutions design. **Limitations.** The study conducted in Finland, the results may differ in a country with different culture and socioeconomic environment. The sample was small, but due to HP's different specialties and longtime experience, was considered representative of a primary healthcare setting.

Serving Health Emergency Responders Through Online Learning – Findings from OpenWHO's Global User Metrics

Heini UTUNEN^a, Ngouille NDIAYE^a, Ursula ZHAO^a, Richelle GEORGE^a,
Melissa ATTIAS^a, Gaya GAMHEWAGE^a
^a*World Health Organization*

Abstract. This poster presents some preliminary findings of the OpenWHO.org platform's global use trends, in terms of the geographical distribution and occupational characteristics of its users. Assessment of user profiles is essential to measure the platform's impact, most notably related to the attainment of its core mission: the provision of life-saving knowledge worldwide. A quantitative study was conducted on the global metrics of OpenWHO's user statistics. Common user categories encompassed a wide range of professional bodies and occupations, both within public health and beyond, ranging from students and volunteers, to WHO staff, to members of international organizations and NGOs. Global tendencies in platform use confirm that the mission of OpenWHO, to provide timely, up-to-date and easy-to-understand lifesaving knowledge to healthcare workers based in-country and responding to outbreaks at the front line, is being met.

Keywords. Knowledge transfer, health emergencies, outbreaks, knowledge to action, online learning, knowledge resources, OpenWHO

1. Introduction

OpenWHO.org was launched in 2017 by the World Health Organization's (WHO) Health Emergencies Programme (WHE). The free, self-paced and open-access online learning platform facilitates the transfer of the latest and most-relevant scientific, technical and operational knowledge to frontline responders. Planning for the worst-case scenario, a pandemic, the platform is designed to host millions of users simultaneously and provide an easy-to-access platform for WHO technical guidance.

This study reveals some user profile characteristics that can be viewed against the global MOOC learner demographics. Veletsianos & Shepherdson (2016) highlight MOOC learners spanning over 194 countries with most users in North America and Europe and a majority being male, 20-40 years old, with a college degree or higher [1]. While OpenWHO user data does not collect educational background, the gross use by country and user profile seems to align with the global MOOC user profiles.

2. Method

Anonymous profile information of over 75 000 users was retrieved from the platform database in the format of spreadsheet. A quantitative analysis was conducted, primarily

focusing on user demographics and geographical presence, as well as affiliations given at the time of first enrollment. A separate analysis was conducted of the geographical information of users enrolled in the 12 most-visited courses, many of which were created in support of past or ongoing responses to global health emergencies.

3. Results

As of September 2019, the platform had 75 000 unique users and 130 000 course enrolments in more than 70 courses, including courses in all UN official languages and 15 other languages. User analysis reveals that OpenWHO is accessed by users in over 190 countries. Half of the platform's users (46%) are located in the five top countries: the United States of America, India, Portugal, Nigeria and Saudi Arabia.

Among the top 20 countries by users, four are experiencing ongoing WHO graded health emergencies – the Democratic Republic of the Congo, South Sudan, Pakistan and Nigeria – and five others are outbreak and epidemic-prone. The data on user location confirm that OpenWHO delivers lifesaving knowledge to those responding to health emergencies anywhere in the world. However, in the top countries list, a total of 11 countries are high-income countries, mainly from North America and Europe. User profiles are majority male and aged 20-40.

Results from the analysis of users' professional profiles highlight the platform's popularity among healthcare workers at the country level in low- and middle-income countries and countries with health events, while the student category is more popular in countries with no WHO-graded emergencies, such as the USA, India and Portugal.

4. Discussion

Real-time health emergencies and outbreaks appear to be driving the platform's popularity in its top countries. OpenWHO has also been successful in achieving yet another one of its aims, to make health-related technical knowledge more accessible to all, including any interested user, evidenced by the fact that the platform's materials are being utilized by staff across ministries of health, the UN, humanitarian organizations and NGOs, as well as healthcare workers, government personnel, volunteers and students. This also shows a keen interest in online learning from countries on all continents.

5. Conclusion

OpenWHO's user analytics suggest that the platform is reaching the world of health emergencies, as per its founding principle. Further analysis of user metrics will follow to understand the use of various languages on the platform and how use may be impacted by different types of health emergencies.

Smartphone Applications for Range of Motion Measurement in Clinical Practice: A Systematic Review

Anne-Violette BRUYNEEL^{a,1}

^a*Department of Physiotherapy, School of Health Sciences, HES-SO/University of Applied Sciences and Arts Western Switzerland, Geneva, Switzerland*

Abstract. The aim of this study was to investigate the validity and reliability of range of motion measurement via smartphone applications. This literature review included 26 articles after the selection process. The validity and reliability analysis showed good mean results (ICC or $r > 0.83$). Thus, in clinical practice, photographic, goniometric and inclinometric smartphone applications can be used to measure joint angle, but with caution for cervical, hip and shoulder motions.

Keywords. Range of motion – application – smartphone - validity – reliability

1. Introduction

Many smartphone applications have been launched in recent years for patient management in clinical practice, as well as range of motion tools. However, before generalizing these tools, it is necessary to know the psychometrics qualities of these new smartphone applications. *The aim* of this study was to provide a systematic review about validity and reliability (intra and inter-raters) of range of motion measurement (upper-limbs, lower limbs and trunk movements) via smartphone application.

2. Study

2.1. Method

The research was conducted, in English, using the following keywords such as « healthy subjects », « phone », « range of motion », validity », « reliability » et « repeatability » on the databases: PubMed/ Medline, ScienceDirect and Pedro. A synthesis was carried out and the qualities of each study was evaluated by the Qare score.

2.2. Results

563 articles about smartphone applications used in healthy subjects were identified. Following the selection criteria, 26 articles were included which are six articles for cervical, thoracic and lumbar motions, 11 for lower limb and 9 for upper limb motions.

¹ Corresponding Author, E-mail: anne-violette.bruyneel@hesge.ch

These studies included 818 healthy subjects. The mean Qarel score for all studies was 7.36/12 (min:6/max:9). The synthesis showed that the for validity was good ($r = 0.83$ [min:0.40, max:0.99]). The intra-rater reliability analysis showed an ICC=0.88 (min:0.05 – max:0.99), investigated by 23 studies. The inter-rater reliability was assessed by 20 studies with a mean ICC result (ICC=0.85 [min:0.07 – max:0.99]). The results highlighted no difference between the type of applications (inclinometer or goniometer) and the phone system (iPhone vs. Android).

2.3. Discussion

This systematic review showed the existence of numerous studies on the psychometric qualities of smartphone applications to measure range of motion in clinical practice for healthy subjects. All studies presented a consistent methodology with the stated objective and tested validity prior to reliability. The data suggest that smartphone with the angle apps is a viable substitute for using a usual goniometer or an inclinometer when measuring angular changes that typically occur when examining range of motion and demonstrate the capacity of multiple examiners to accurately use smartphone-based angle apps. The trunk, upper limb and lower limb range of motion were assessed for validity and intra-rater reliability in healthy subjects. The inter-rater reliability has not been studied for hip movements. The best values were obtained for the wrist, the elbow, the ankle, the knee, the lumbar and thoracic range of motion, whatever application was used. No study at the time of the review was found on the finger movements.

Figure 1. Synthesis of validity results.

Social Media Mining for Postpartum Depression Prediction

Alina TRIFAN^{a,1}, Dave SEMERARO^b, Justin DRAKE^b, Radek BUKOWSKI^c and José Luís OLIVEIRA^a

^aDETI/IEETA, University of Aveiro, Portugal

^bTexas Advanced Computing Center, University of Texas at Austin, USA

^cDell Medical School, University of Texas at Austin, USA

Abstract. This study investigated the feasibility of a postpartum depression predictor based on social media writings. The current broad use of social media networks generates a large amount of digital data, which, when coupled with artificial intelligence methods, have the potential to disclose significant health related insights. In this paper we explore the use of machine learning for prediction of postpartum depression on a corpus created from Reddit posts.

Keywords. postpartum depression, social media, machine learning, mental health, women's health

1. Introduction

Despite the widespread use of prenatal care and the increasing adoption of ante- and post-partum depression screening tools, post partum depression (PPD) often goes undiagnosed or untreated. For example, Ko et. al [1] estimated nearly 50% of of pregnant women who experienced a major depressive episode in the past year received treatment, and Vesga-Lopez et al. [2] estimated the prevalence for untreated, postpartum mood disorders to be 85%. Clearly, there is an opportunity to enhance existing screening tools and protocols to detect PPD, and to promote better treatments. Here, this study considers the use of social media as an early intervention tool by accelerating the potential diagnosis of mothers at risk of PPD and thus the implementation of early interventions.

2. Methods

We build a corpus of postpartum depression related posts matched with control posts using the Reddit API². We collected public posts from PPD related subreddits, along with posts from parenting subreddits as controls. We conducted this study as a binary classification question. Prior to post classification, the preprocessing of the Reddit posts followed standard approaches in text classification. The posts were lowercased and tokenized, after removing all non-alphabetic characters. Stopwords were filtered. We considered Bag of Words (BoW) features as predictors and we applied counts and tf-idf based feature weighting. All experiments were managed using the scikit-learn machine learning framework [3]. Additionally, our experiment targeted the relation between gen-

¹Corresponding Author: alina.trifan@ua.pt

²<https://www.reddit.com/dev/api/>

eralized depression and postpartum depression. For this purpose, we employed a model previously trained on a dataset containing writings of depressed Reddit users, matched with control users, the Reddit Self-reported Depression Dataset (RSDD) proposed by Yates et al. [4].

3. Results

We performed experiments with two different estimators, under different configurations, Passive Aggressive and Perceptron, as well as the model trained on RSDD. We present the best results in Table 1. These results demonstrate that it is possible to distinguish postpartum depression related context from generalized user writings with quite a high degree of confidence. Moreover, as expected, there is a clear connection between the writing style of people suffering from depression, independently of their age and sex, and recent mothers that go through postpartum depression.

Table 1. Comparative results on classifying postpartum depression.

Method	Prec.	Rec.	F1	Acc
Perceptron	0.83	0.87	0.85	0.89
Passive Aggressive (loss=sqrt_hinge)	0.90	0.89	0.9	0.93
RSDD trained model	0.95	0.43	0.6	0.8

4. Conclusions

The preliminary results that we present in this paper serve as a motivation for safely exploring social media networks as enablers of early risk interventions for mothers suffering from postpartum depression. As future work, we will focus on extending the collected corpus with more user histories and identifying psycholinguistics features that differentiate the postpartum depression group from the control group within our corpus.

Specification and Distribution of Vocabularies Among Consortial Partners

Mirko GRUHL^{a,1}, Ines REINECKE^a and Martin SEDLMAYR^a

^aCenter for Medical Informatics, Institute for Medical Informatics and Biometry, Carl Gustav Carus Faculty of Medicine, Technische Universität Dresden, Dresden, Germany

Abstract. Due to the variety of different software systems and disparate observational databases, the need for a uniform data representation rises. Common data models (CDM) support the harmonisation of data. A powerful but compact software setup and a minimum vocabulary set has been composed via Docker to facilitate analysis of data across ten university hospitals. The presented approach also creates the possibility to use a concise database which is easy to deploy.

Keywords. vocabulary, OMOP, Docker, reproducible, data sharing

1. Introduction

To overcome the issues caused by heterogeneous databases, common data models (CDM) support the harmonisation of data. As part of the MIRACUM initiative [1], all data should be transformed into the Observational Medical Outcomes Partnership (OMOP) CDM [2]. This yields a universal format and a corporate representation with corresponding terminologies, vocabularies and coding schemes. The outcome of the implementation is the utilisation and analysis of data across ten university hospitals and the possibility to use the OHDSI suite of applications and exploration tools [3] in one ready-made distribution.

2. Method

First, a minimal vocabulary for a provided synthetic test data was specified by downloading the full set of standardised vocabularies and based on local data and mappings the actually needed concepts were determined. The next step comprised the enhancement of the minimal vocabulary to meet the requirements of the core data. Based on the work of Maier et al. [4] who integrated the ICD-10-GM (International Classification of Diseases, German Modification) and the "Operationen- und Prozedurenschlüssel" (surgery and procedure key) the vocabulary set was cleaned from unnecessary vocabularies that have no relevance in Germany. Finally, a system was planned and realised

¹Corresponding Author: E-mail: mirko.gruhl@uniklinikum-dresden.de

using Docker. The software bundle includes the OHDSI WebAPI [3] which contains all services that can be called from Atlas [3]. Additionally, the R Methods Library (<https://github.com/OHDSI/Broadsea-MethodsLibrary>) and Achilles [3] were applied. The databases were generated reproducibly via scripts and shared for the partners as Docker volumes which differ in the setup and size to meet different requirements.

3. Results

All system dependent volumes and images are hosted in a common registry and self-hosted cloud storage, respectively. The developed system uses a Docker compose file which is derived from the OHDSI Broadsea [5] tool set. Thus, the whole setup can be deployed in minutes using simple docker commands. The project is publicly available via GitLab (<https://gitlab.miracum.org/gruhlmi/ohdsi-omop-v5>).

4. Discussion

The system can be reproducibly deployed. Broadsea was chosen as a basis and customized so that a complete database with all needed content to start work with OMOP is available from one hand. The OMOP CDM was selected because of initial experiences and a big community. The compilation of the provided minimum vocabulary fits the requirements for healthcare research in Germany. Hence, every consortial member can start up an initial database with optimal memory utilisation. The use of the vocabulary is subjected to the license agreement and expects individual responsibility by every end user. Apart from the promising approach there are still challenges regarding the particularities of German classifications and procedures and the mapping to standard vocabularies.

5. Conclusion

The successful realisation of the objectives yields a powerful system which uses OMOP as starting point for federated healthcare research among ten MIRACUM sites. Further work on this topic will include the upgrade of the components and a strategy development to update the vocabularies automatically. The work is part of the project MIRACUM, funded by the German Ministry of Education and Research (FKZ 01ZZ1801L).

Standardized Communication Using FHIR and SNOMED CT in Treatment of Diabetic Foot Syndrome Within the Project iFoot

Dominik LUDMANN^{a,1}, Elisabeth PANTAZOGLOU^a and Hubert OTTEN^a
^a*Hochschule Niederrhein, University of Applied Sciences, Faculty of Healthcare*

Keywords. Interoperability, Standardization, Diabetic Foot Syndrome, FHIR, SNOMED CT

1. Introduction

About 15% of patients with diabetes mellitus develop a diabetic foot syndrome (DFS) during their lifetime. Complications caused by DFS are the main reason for hospital admissions and amputations [1] [2]. The number of amputations in DFS patients is estimated at 40,000 per year and accounts for approximately 70% of all amputations performed in Germany. The total costs of treatment in Germany amount to approximately 2.5 billion euros per year. In order to reduce expenses, the DFS needs optimal care and treatment [3]. The data and information transfer is a decisive aspect in ensuring the quality of care and patient safety. The development and use of modern e-health applications is therefore a promising approach for the interdisciplinary treatment of DFS. The iFoot research project focuses on an optimized approach to DFS medical and nursing care. In 2005 the German Federal Association for Statutory Health Insurance Physicians (Kassenärztliche Bundesvereinigung, KBV) introduced a specification for the electronic Disease Management Programme (eDMP) for patients with Diabetes mellitus type 1 and type 2. The aim of the eDMP is the structured treatment of chronically ill patients with the help of defined care processes based on defined therapy goals and to improve communication and care between service providers and the inpatient and outpatient sectors of the German health care system [4].

2. Methods

Since the current specification of the eDMP Diabetes mellitus type 1 and type 2 does not provide the use of terminology standards, some excerpts of the eDMP are represented in this paper using the internationally recognized IT standards Fast Healthcare Interoperability Resources (FHIR) and the Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT). FHIR is an international standard of Health Level Seven (HL7) for the exchange of digital health data [5]. SNOMED CT is a multilingual medical terminology system that is already used in over fifty countries for the electronic representation of clinically relevant terms [6]. In the context of this ongoing work, an example will be used to illustrate the possibility of mapping the

¹ Corresponding Author, E-mail: dominik.ludmann@hsnr.de.

eDMP diabetes mellitus type 1 and type 2 according to the guidelines of the KBV with international standards.

3. Results

As an example, the mapping of the specified data fields for *further risks for ulcer* is carried out in an FHIR-Observation resource via SNOMED CT code *714664001 (At Risk of diabetic foot ulcer)*. Within the *Observation.valueCodeableConcept* element, it is possible to define the given values in coded form. For this purpose, the KBV defines the following seven concepts (Table 1):

Table 1. Mapping examples from eDMP Diabetes mellitus to SNOMED CT

Code	Term	Code System
373066001	Yes	SNOMED CT
373067005	No	SNOMED CT
229844004	Deformity of foot	SNOMED CT
75134009	Not examined for	SNOMED CT
396228006:363713009=255345002	Hyperkeratosis with bleeding	SNOMED CT
128926000:255234002=371087003	State after ulcer	SNOMED CT
128926000:255234002=180030006	State after amputation	SNOMED CT

4. Discussion

The current results of this ongoing work demonstrate that the use of FHIR and SNOMED CT is well suited and feasible for the annotation of the eDMP Diabetes mellitus type 1 and type 2 specification, although the annotation of the dataset poses some challenges due to a lack of information from KBV. Furthermore, as shown in Table 1, for more complex data elements (e.g. *Hyperkeratosis with bleeding*), post-coordinated SNOMED CT concepts had to be built. By using standardized terminologies, future implementations of the eDMP for Diabetes mellitus could reduce redundancies in data collection and storage. Thus, eDMPs could become an integral part of an interoperable eHealth landscape in the German health care system.

Strategy for the Analysis and Visualization of Electronic Medical Record Data for Public Hospitals in the City of Buenos Aires

Tomas GALLUZZI ^a, Marina RIDAO ^a, Santiago ESTEBAN ^a

^aHealth Information Management and Statistics Office, Ministry of Health, City of Buenos Aires, Argentina.

Abstract. Through the development of a dashboard with participative methodology we present a centralized strategy to analyze and visualize EMRs data for the management of 15 public hospitals from Buenos Aires City. This approach could constitute an efficient option for public health systems from developing countries.

Keywords. Electronic medical records, R software, data visualization, public health care.

1. Introduction

The availability and increasing amounts of data from electronic medical records (EMRs) give an important boost for information-based health service management. However, the exploitation of information to improve health care systems in low-income countries is scarce [1]. In June 2016, the Ministry of Health of the city of Buenos Aires began to implement an EMR system at the primary healthcare level and progressively expanded into general hospitals [2]. Nevertheless, hospitals do not have human resources with the skills to conduct data analysis from EMRs. To minimize these technical barriers and support decision-making processes, AGISE¹ designed a centralized and participative strategy to create dashboards for the management of 15 public hospitals.

2. Methods

The centralized component of the strategy included the analysis and development of the dashboards. R software was chosen for statistical computing as it is open-source and free tool. The following libraries were used for visualization: highcharter, to create charts, leaflet, to create interactive maps, and rmarkdown, to render the dashboards. AGISE scheduled meetings with the managers of the three hospitals with the highest levels of EMR implementation in order to define and design new indicators and review testing versions in a participative manner. Unstructured individual exchanges with each manager were conducted for indicator prioritization and selection.

¹ Health Information Management and Statistics Office (AGISE) whose objective is to provide timely and quality data from EMR through qualified professionals with heterogeneous profiles.

3. Results

After reaching a consensus on what indicators and information should be included, the final version was elaborated and then distributed to the remaining hospitals. The dashboard contains an initial page (Fig.1) divided into four sections: Demographic Data (Fig.2), Registration, Outpatient Consultations, and Emergency Room Consultations (Figs.3 and 4). New versions of the design of the dashboard are incorporated on an ongoing basis as more hospital areas implement EMR systems.

4. Discussion

Although management frameworks recommend decentralized decision making for hospital autonomy and governance [3], the centralized and participative approach may have advantages in a context of low-qualified human resources for data analysis.

5. Conclusion

This action plan could constitute a good option for decision-making processes in public hospitals using EMR information with available resources in health systems from developing countries. Next steps will include evaluation of dashboard use and utility.

Figure 1. Initial page for each hospital.

Figure 2. Demographic Data.

Figure 3. Outpatient Consultations.

Figure 4. Outpatient Consultations.

Strengthening Behavior and Social Functioning Among Persons with Autism Spectrum Conditions Using Artificial Intelligence and Behavioral Activation: Protocol for the Well-Being and Health for Loved ones with ASD (WHOLE) Psychosocial Pilot Randomized Controlled Trial

Pierre BOWRIN^a and Usman IQBAL^{b,1}

^a *Global Health and Health Security Doctoral Program, College of Public Health, Taipei Medical University, Taipei, Taiwan*

^b *Global Health and Health Security, College of Public Health, Taipei Medical University, Taipei, Taiwan*

Abstract. Although a proportion of families and communities in low resource settings continue to provide care to loved ones with autism spectrum conditions, many of the affected persons remain undiagnosed and without access to proven therapies due to high treatment cost and cultural pressures, in particular. Use of conversational agents on mobile phones in combination with behavior activation home care may provide an innovative, culturally appropriate and affordable platform for strengthening behavior and social functioning outcomes, in addition to an opportunity for participation of the persons with autism spectrum conditions in the intervention development process. We aim to assess the effectiveness of an intervention that incorporates artificial intelligence conversational agent technologies and behavioral activation therapy techniques.

Keywords. Artificial Intelligence, Autism Spectrum Disorders, Conversational Agent, Chatbot, Psychosocial, Social functioning, Randomized Control Trial

1. Introduction

Autism Spectrum Disorders (ASD) are the fastest growing developmental disability [4, 5] that affects approx. 1% of the world population [2] and impacts behavioral and social functioning deficits such as social motivation, social anxiety, social cognition, and social skills [3].

¹ Corresponding Author, E-mail: usmaniqbal@tmu.edu.tw.

Autism policy and intervention research stakeholders advocate for psychosocial interventions that reduce core symptoms and improve adaptive skills; empower families and local communities; are applicable for low resource settings and actively incorporate persons with ASD in the research process and dissemination of findings [1], but interventions with such components remain underutilized. Therefore, this study aims to assess the feasibility of conducting a randomized control trial (RCT) evaluating the effectiveness of a behavior and social functioning intervention using artificial intelligence via a conversational agent or chatbot and behavioral activation with persons with Autism Spectrum Conditions.

2. Methods and Analysis

The Well-being and Health for Loved Ones with Autism Spectrum Conditions (WHOLE) intervention is a pilot, single-blinded, randomized controlled trial evaluated over 12 weeks, with 6 and 12-month follow-up periods to assess the feasibility, social and economic value of the intervention. Sixty youth/young persons will be recruited and randomized into intervention and control groups. Participants will be selected, in part, via the Emotional and Behavioral Screener instrument from the undiagnosed ASD population. Two separate pilot RCTs will be conducted in Saint Kitts & Nevis and Republic of China (Taiwan). Analysis of covariance (ANCOVA), descriptive statistics and social return on investment (SROI) analysis methods will be employed.

Abstract. TEDIS, an information system dedicated to patients affected with neuro-developmental disorders including autism, focuses on patient data generated during in-depth clinical assessment in nine expert centers in Ile-de-France region. Long term partnership involving methodologists and domain experts is necessary to support quality data production and analyses and to guarantee quality data and information governance in a domain characterized by frequent evolutions in clinical assessment instruments and in diagnostic criteria and classification.

Keywords. Information model, data governance, information governance, DSM-5, ICD-11, Autism Spectrum Disorder, Neuro-Developmental Disorder.

1. Introduction

Autism spectrum disorder (ASD) is a neurodevelopmental condition characterized by persistent difficulties in social communication and interaction, alongside with restricted, repetitive behavior patterns and interests [1]. The diagnosis “*is still made solely on the basis of self/informant reports of behavior according to diagnostic*

¹Corresponding Author, mohamed.bensaid@aphp.fr, mohamed.ben-said@ext.paris-descartes.fr.

criteria in the *Diagnostic and Statistical Manual of Mental Disorders [DSM-5]* or the *International Classification of Diseases [ICD-10]*” [2]. Psychiatric experts from the nine “Centres de Diagnostic et d’Evaluation de l’autisme” or (CDE) in Ile-de-France region, gathered with methodologists in a professional network to manage in a dedicated primary data source, valuable information resuming in-depth, multidisciplinary and psychopathological ASD’ patients’ assessment. The objectives are to improve knowledge about ASD disorders, follow-up patient cohorts and to improve patient care, decision making, and research. The process converged to the TEDIS project [3] supported by the regional public health agency, academic institutions and the regional ASD resources association.

2. Methods

An agreed-upon chart delimits the contours of the TEDIS project and defines policy for data information governance. An application system was developed to facilitate ASD’ patient data collection and quality control. Aggregated data are analyzed and described in an automatic feedback report [4]. Ethical authorizations facilitated Internet deployment via a Certified Health and Personal Data Internet Hosting Provider [5].

3. Results

An active expert network federated around ASD’ patient data production, analyses and maintenance. Up-to-date, 978 controlled ASD patient records in TEDIS’ cohort provide a quality data source supporting research and public health decision making.

4. Discussion / Conclusion

Challenges need being addressed to maintain the professional network active to capture domain expertise, to insure cohort progress and to keep the data model up-to-date with evolutions in diagnostic criteria (DSMIV/DSM-5) and classifications (ICD10/ICD11).

Telemedicine Interventions for the Management of Diabetes: A Systematic Review and Meta-Analysis

Stine HANGAARD^{a,1}, Sisse H. LAURSEN^b, Flemming W. UDSEN^a, Peter VESTERGAARD^c, and Ole HEJLESEN^a

^a*Department of Health Science and Technology, Aalborg University*

^b*University College of Northern Denmark, Department of Nursing*

^c*Steno Diabetes Center North Denmark*

Keywords. Telemedicine, diabetes, telemonitoring

1. Introduction

Telemedicine is often suggested as a promising approach to support patients with diabetes [1,2]. Telemedicine interventions in diabetes may include video consultations, text reminders, telemonitoring, etc. [3,4]. However, the effectiveness of diabetes-related telemedicine interventions in regards to patient-related outcomes needs evaluation.

The rapid development within telemedicine emphasizes the need for a new review. Moreover, previous systematic reviews describing the effectiveness of telemedicine in diabetes management focus on a specific type of telemedicine [5,6], a specific type of diabetes [7,8], specific comparators [2,6], or specific outcomes [2,9]. Thus, the present review has a broad scope with an eye to performing an exhaustive review within the field. The present systematic review and meta-analysis aims to evaluate the effectiveness of telemedicine interventions versus any comparator on diabetes-related outcomes among adult patients with diabetes.

2. Method

The present review considers studies that include adult subjects with a diagnosis of diabetes (type 1, 2, or gestational). Studies that evaluate telemedicine interventions are considered. These telemedicine interventions may include various technologies, and the remote communication may be managed by various health care professionals, trained peers, or be fully automatic. The review considers randomized controlled trials comparing a telemedicine intervention to any control that does not include telemedicine. The considered outcomes include all patient-diabetes related outcomes. Peer-reviewed full-text papers in English, Norwegian, Danish, and Swedish are considered.

¹ Corresponding Author; E-mail: svh@hst.aau.dk

A thorough search was performed in PubMed, CINAHL, EMBASE, and the Cochrane Library Central Register of Controlled Trials (CENTRAL). To provide an estimate of the treatment effect, the studies will be pooled via statistical meta-analysis.

3. Results

The search identified 11,759 potential papers. After removal of duplicates, 7,558 papers remained. These papers underwent screening (title/abstract), and 941 remained for full text reading. This resulted in a final sample of 218 papers. Preliminary results indicate that effects are limited in regards to type 1 diabetes and gestational diabetes. However, the effect in regards to type 2 diabetes shows more promise.

4. Discussion

The review is strengthened by the fact that the search of literature is very exhaustive. An expected limitation is the limited heterogeneity between telemedicine studies, as the studies differ in use of technology, organizational setup, etc., which complicates the comparison of studies.

5. Conclusion

The present review may add value to the existing evidence base by providing an exhaustive review of telemedicine interventions in diabetes. Further results will follow.

The ‘Back Office’ of a Dispensing Cabinet: Technology and Work Contributing to Medication Safety

Valentina LICHTNER^{a,b,1}, Mirela PRGOMET^b, Bryony Dean FRANKLIN^{a,c},
and Johanna I WESTBROOK^b

^aDepartment of Practice and Policy, UCL School of Pharmacy, UK

^bCentre for Health Systems and Safety Research, AIHI,
Macquarie University, Australia

^cCentre for Medication Safety and Service Quality, Pharmacy Department,
Imperial College Healthcare NHS Trust, UK

Abstract. Automated dispensing cabinets in clinical wards may contribute to improving safety by reducing the likelihood of medications not being available when needed. However, achieving this safety benefit is dependent on a ‘back office’ sociotechnical infrastructure that combines semi-automated processes with mindful, resilient work practices.

Keywords. Patient Safety, Hospital Drug Distribution Systems.

1. Introduction

Missed medication doses (omissions) are a common medication administration error and negatively impact the safety of hospital inpatients (e.g. [1, 2]). One reason leading to omissions is unavailability of medication on the ward at the time of need [3].

Ward-based automated dispensing cabinets (ADCs) can assist with the management of ward medication stock (‘imprest’) and thus may reduce the number of doses omitted due to unavailability [4]. However, little is known about the ‘behind the scenes’ work that contributes to this effect. In this poster we describe and discuss the sociotechnical system that lies behind ward-based ADCs. This sociotechnical system usually remains invisible [5] to ADC users in clinical areas.

2. Methods

We draw on ethnographic research carried out in hospitals in the UK and in Australia. The UK study was conducted in an adult hospital in 2016-17, while the study in Australia is in progress. Both studies were wide-ranging, focused on clinicians’ medication work, with attention paid to medication activities carried out by pharmacy staff and technology such as ADCs. Activities were observed both in pharmacy areas

¹ Corresponding Author. Email: valentina.lichtner@mq.edu.au

and clinical wards. We interviewed pharmacists and technicians, as well as pharmacy managers and IT staff. In this analysis, we focus on pharmacy processes for management of imprest medications in ADCs. Our analysis was influenced by the *sensitivity to operations*, *preoccupation with failures* and *resourcefulness* that characterize resilient activities in high-reliability organizations [6], and by the literature on infrastructures in organizations [7].

3. Findings and discussion

ADCs are one of the many information technologies (IT) hospital pharmacies have in place to manage medication stock. Such IT include stock management applications, or systems to connect with manufacturers and wholesalers' catalogues. Some IT functionalities are automated: for example, the ADC alerts pharmacy staff of medications low in stock; a stock management system can be set up to automatically re-order routine stock from wholesalers.

Effective use of these systems, however, cannot rely exclusively on automation that works on data about past use and embedded rules. Instead, it requires pharmacy staff to pay attention to any emerging risks associated with the availability (or lack thereof) of different types of medication, foreseeing supply chain conditions, and resourcefulness in solving problems or constraints.

This is invisible, mindful [6] work of pharmacy staff behind the scenes of an ADC, that makes the replenishing of ADCs' imprest medication stock look seamless from the clinical areas, most of the time.

4. Conclusion

The 'backoffice' of hospital ADCs is a sociotechnical infrastructure that combines semi-automated processes with mindful, resilient work practices. It is this combination, rather than the technology on its own, that is likely to reduce the frequency of omitted doses for hospital inpatients.

Abstract. Noncommunicable diseases (NCDs) were caused by risk factors also rising rapidly and killed more people. This study aimed to explore and determine the prevalence and distribution of alcohol and tobacco use as NCDs's risk factors. We used a cross-sectional survey on Health dataset between October 2013 and April 2017 of people who were 13 years old and older. This study was investigated included demographics, alcohol consumption and tobacco use. This study found risk of NCDs 49.07%. The majority of risk factor were men (50.2 %), age_group were 40-59 years old(24.4%), The most were men having diabetes mellitus family (43.0%), hypertension family (17.9 %), alcohol consumption (26.9%), tobacco use (19.0%), most of the women were high blood pressure (23.0%), high blood sugar level (33.3%), overweight and obesity (23.4%), waist was over (22.5%) and high total cholesterol (21.4%), alcohol consumption among the gender 37.8%, most were male (26.9%), age_group mostly 45-59 years old (19.3 %), married (23.1%), agricultural (29.7%), primary school (29.7%). The prevalence of risk factors, most risk factors was tobacco use in men (18.9%), OR 16.789, (95%CI, p-value<.001), alcohol consumption were men (26.9%), OR 3.934 (95%CI, p-value<.001).

Keywords. Health Data Centre, Health Dataset, Risk Noncommunicable diseases

1. Introduction

Noncommunicable diseases (NCDs) are incurable chronic diseases. People were death by NCDs caused a total of 41 million every year, up to 71% of all deaths globally, most death located in low and middle-income countries. The behavioural risk factors and metabolic factors are caused the major factors [1]. and underlying risk factors [1, 2]. Thailand had increased incidence of NCDs and death around 500,000 cases (71.0%) of all death[3]. Thai's hospitals collected electronic health data records and linkage with Health Database Centre (HDC) [4] This study aimed to explore and determined alcohol consumption and tobacco use in the prevalence associated with the risk factors of NCDs[5].

¹Corresponding author: E-mail: kampol.khe@msu.ac.th.

2. Methodology

We used a cross-sectional survey and data from electronic health data records were verified quality to ensured from all hospitals on Health Data Centre (HDC) database of Si Sa Ket Provincial Public Health. This studied data contained demographics, physical measurements, biological measurement. This dataset excluded all cases with missing, duplicate, error information and a case that a physician had diagnosis be NCDs patient. We selected population by purposive sampling who was 13 years old and older.

3. Results

Found risk people 49.07 %, were men (50.2 %), age_group were 40-59 years old(24.4%)(mean 50.97, S.D. 21.747), men having diabetes mellitus (43.0%), hypertension family (17.9 %), alcohol consumption (26.9%), tobacco use (19.0%), most of the women were high blood pressure (23.0%), high blood sugar level (33.3%), overweight and obesity(23.4%), waist was over (22.5%) and high total cholesterol (21.4%). alcohol consumption among the gender 37.8%, mostly were male (26.9%), female(10.9%), the group of 45-59 years old (19.3 %), married (23.1%), agricultural (29.7%), primary school (29.7%). The prevalence of risk factors, most risk factors was tobacco use in men (18.9%), OR 16.789, (95%CI 16.399-17.188, p-value<001), alcohol consumption were men (26.9%), OR 3.934 (95%CI 3.885-3.983, p-value<.001).

4. Discussion and Conclusion

A large electronic health data were studied from the Health Data Centre (HDC), it was a linkage of all Health server database permitted for administrators to verified data and sharing. We found a population that registered, but more cases were missing a health check data and electronic health data was an error, missing and duplicate. People who risk NCDs and the majority were men. Health evidence based on electronic health data could be support and provides health policy maker and effort to health personnel.

Abstract. An overarching WHO-FIC Content Model will allow uniform modeling of classifications in the WHO Family of International Classifications (WHO-FIC) and promote their joint use. We provide an initial conceptualization of such a model.

Keywords. ICD, ICF, ICHI, Family of International Classifications

1. Introduction

The 11th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-11) represents a fundamental change in the methodology for developing new classifications at the World Health Organization (WHO). Major departures from past ICD revisions include an information model of ICD categories called the Content Model, the maintenance of all-inclusive knowledge about ICD-11 content, called the Foundation, and the ability to create specialized classifications, called linearizations, for a range of use cases.

In addition to ICD, the WHO-FIC reference classifications include the International Classification of Functioning, Disability, and Health (ICF)[1], and the emerging International Classification of Health Interventions (ICHI)[2]. The goal of this work is to develop a generalized WHO-FIC Content Model that defines the information structure of the entities in the classifications and their semantic roles.

2. Method

The Content Model defines the types of entities and relationships in the WHO-FIC Foundation. We analyzed the structure of ICD, ICF, and ICHI to determine an

¹Corresponding Author, Samson W. Tu, Stanford University, USA; E-mail: swt@stanford.edu.

overarching conceptualization.

3. Results

We conceptualize the generalized WHO-FIC Content Model as consisting of the following: (1) *Codable entities* in a classification: These are the categories that represent phenomena that a classification is designed to encode. For ICD, diseases, disorders, and injuries are examples of codable entities. For ICHI, health interventions are the codable entities. For ICF, functioning situations (defined in terms of ICF domains and the impairment/limitation/restriction qualifiers) and environmental factor roles, will be codable entities. (2) *Structural component*: These are the entities that help to define the meaning of codable entities. For ICHI, targets, actions, and means are the structural components of health interventions. For ICF, body structure, body function, activities and participation, and environmental factors are the structural components that help to define the functioning situations and environmental factor roles that ICF is designed to code. No structural component is defined for ICD at this time. (3) *Defining qualifiers*: In ICF, some attributes, such as the extent of impairment qualifier, are necessary for the definition of codable entities. (4) *Extension codes*: These are entities that can be used to refine the codable entities. (5) *Properties of the classification entities*: These include informational properties, such as title and definition, and post-coordination properties that represent axes along which the entities can be defined logically or specialized.

In addition, a *post-coordination model* specifies how the structural components, defining qualifiers, and extension codes can be used, in conjunction with post-coordination properties, to define and refine codable entities. Finally, a *linearization model* specifies what entities and relationships are necessary to describe any linearization in the Foundation. It allows the specification of the entities that should be included in a linearization, the post-coordination axes are allowed or required in a given linearization, and constraints on the values of the post-coordination axes in a linearization.

4. Discussion

ICD and ICHI can easily be formulated in this framework. For ICF, the introduction of the concept of codable entities as composed from ICF domains and qualifiers formalizes what has been informally defined. The post-coordination model defines the semantic roles that each type of entity plays in the information model. In conclusion, the unification of WHO reference classifications in a common modeling framework is promising and provides a solid foundation for future enhancements of these classifications.

Towards an Ontology for Trustful mHealth Apps

Hanane DERBOUZ ROUIBETE and Stefano BONACINA^{a1}

^aHealth Informatics Centre (HIC), Department of Learning, Informatics, Management and Ethics, Karolinska Institutet, Stockholm, Sweden

Abstract. A unified and integrated approach to represent mHealth apps and their characteristics is currently lacking. To fill this gap, the overall purpose of this project is to develop an ontology, to help address the objective of building 'trustful' mHealth apps. This paper is a brief presentation of the followed methods, and the preliminary results of the research, i.e. a first version of that ontology.

Keywords. mHealth apps, ontology development process, Unified Modeling Language Class Diagrams, Web Ontology Language, Protégé

1. Introduction

Despite the continuous growth of mobile health applications (mHealth apps), the available ones are problematic, due to the lack of a unified framework, specially devised for their development and quality assessment [1]. This prevents a common adoption of mHealth apps in healthcare delivery, as they might be risky. Massive accreditation programmes of mHealth apps seem to be unfeasible [2], though assessment frameworks have been developed [3] and development of standards is in progress (e.g. HL7 cMHAFF [4]). Alternative strategies for quality assessment have to be explored, as well. Biomedical Informatics research has demonstrated a successful development of ontologies. As defined in Computer Science, they are sets of concepts and their relationships, to represent a domain, by sharing structured, computable knowledge (e.g. the Gene Ontology [5], for genes' annotation). This project aimed to propose an ontology to help address the objective of building 'trustful' mHealth apps, sharing common understanding of the concepts, among people and applications.

2. Method and Results

We applied a combination of methods to develop an ontology for mHealth apps. The Design Science research methodology [6] has been involved as a main theory in the research process. We performed a literature search and analysis to identify features and characteristics of mHealth apps (search strings: "ontology development", "mHealth", "mHealth apps", "mobile apps", "content analysis", "methodologies for ontology development", sources: PubMed, Web of Science, and Google Scholar; time span:

¹ Corresponding Author,. Email: stefano.bonacina@ki.se.

2013-2017, language: English). The Unified Process for ONtology building (UPON) [7] and the Ontology Development 101 [8] guide have been applied for implementing the ontology. Protégé 5.2.0 and Astah UML have been used to represent the ontology by OWL 2.0 language and UML class diagrams, respectively. Finally, to identify subsumption relationships between classes, HermiT OWL Reasoner has been applied.

Sixteen papers were selected and analysed. The developed ontology includes 13 concepts and their relationships. Main concepts are “mHealth app” (with its features), “User”, “Development Process”, “Developer”, “Organisation”, “App Publisher”, and “App Documentation”, with sub-concepts. Main relationships are “use”, “assess”, “recommend”, “develop”, “is_supported_by”, “regulate”, and “provide”. OWL 2.0 format and UML class diagrams have been created, and consistency achieved.

3. Discussion and Conclusion

A first edition of an ontology for mHealth apps has been implemented, and its consistency achieved. Compared to past research [9], in this study mHealth apps and their development were the focuses, including OWL and UML format of the ontology.

This work has certain limitations; firstly, only two researchers performed the development. Secondly, literature from 2013 to 2017 was considered to identify concepts and relationships. Future work addresses involving more researchers and including updated literature.

4. Acknowledgments

This research has been supported by the Health Informatics Centre (HIC), LIME Department, Karolinska Institutet, Stockholm, Sweden.

Towards Prediction of Type 1 Diabetes Patients Who Fail to Achieve Glycemic Target

Morten Hasselstrøm JENSEN^{1a,b}, Simon CICHOSZ^a, Ole HEJLESEN^a, Irl.B. HIRSCH^c, Peter VESTERGAARD^{a,d}

^aSteno Diabetes Center North Denmark, Aalborg University Hospital, Denmark

^bDepartment of Health Science and Technology, Aalborg University, Denmark

^cDepartment of Medicine, University of Washington, Seattle WA

^dDepartment of Clinical Medicine, Aalborg University, Denmark

Abstract. In this study, we investigated which predictors from people with type 1 diabetes at initiation of intensive treatment that increase the risk of not achieving glycemic target. Data from a clinical trial with type 1 diabetes people ($n=460$) were used in a logistic regression model to analyze the effect of the predictors on achievement of glycemic target. Results indicate that age, smoking, glycosylated hemoglobin, 1,5-anhydroglucitol and fluctuation from continuous glucose monitoring are predictors of achievement of glycemic target, which can be used in an algorithm to predict people who fail to achieve glycemic target.

Keywords. Type 1 diabetes, prediction, continuous glucose monitoring

1. Introduction

Today's guidelines, such as, American Diabetes Association's Standards of Medical Care in Diabetes – 2019[1] recommend intensive treatment for diabetes patients to achieve a glycosylated hemoglobin (HbA_{1c}) level of less than 7% (54 mmol/mol). However, it is challenging for people with type 1 diabetes to achieve this glycemic target, and a too aggressive treatment increases the risk of severe hypoglycemia[2]. Prediction at initiation of intensive treatment of those who will fail to achieve target would enable an alternative personalized treatment with the potential of being more effective and safer. This study sought to investigate which predictors from people with type 1 diabetes at initiation of intensive treatment that increase the risk of not achieving glycemic target.

2. Method

Data from people with type 1 diabetes ($n=460$) enrolled in the Onset 5® trial by Novo Nordisk. Participants were on average 43 years old, 57% male, had a diabetes duration of 24 years, a body mass index of 26 kg/m² and an HbA_{1c} of 7.5% (58.5 mmol/L) at baseline. 359 (78%) of the participants did not achieve $HbA_{1c} < 7\%$ after 16 weeks of treatment. Time of randomization defined baseline and initiation of intensive insulin

¹ Corresponding author: e-mail: mhj@hst.aau.dk

treatment. A logistic regression model was constructed to analyze the effect of a variety of predictors at baseline on achievement of $\text{HbA}_{1c} < 7\%$ (Y/N) after 16 weeks of treatment. Predictors at baseline included age (stratified in 18-25, 25-35, 35-50, 50-65 and >65 years), gender, diabetes duration, body mass index, HbA_{1c} , smoking status, fluctuation from continuous glucose monitoring, 1,5-anhydroglycitol (1,5-AG) and fasting plasma glucose. Odds ratios (OR) are presented with 95% confidence intervals (CI).

3. Results

Higher age resulted in an increased risk of not achieving target (50-65 vs 18-25 years OR: 3.5, 95% CI: 1.3-9.6). Not surprisingly, higher HbA_{1c} at baseline increased the risk as well (OR: 14.7, 95% CI: 7.2-30.0). Being a smoker resulted in a 4-fold increased risk of not achieving target (OR: 4.0, 95% CI: 1.2-13.4). Increase in 1,5-AG resulted in a decreased risk (OR: 0.89, 95% CI: 0.87-1.01), whereas increased fluctuation in CGM increased the risk (OR: 1.34, 95% CI: 0.77-2.33), however, none of them were statistically significant. An analysis without fluctuation resulted in a statistically significant association between 1,5-AG and achieving glycemic target (OR: 0.87, 95% CI: 0.77-0.99).

4. Discussion

In this study, higher age affects ability to achieve glycemic target irrespective of diabetes duration. Furthermore, being smoker is associated with not achieving target, which is confirmed by Peng et al.[3]. Higher 1,5-AG level decreased the risk of not achieving target. Blood concentrations of 1,5-AG decreases during time of hyperglycemia, and a higher 1,5-AG level at baseline is thus a reflection of a better control with less glycemic variability. Furthermore, findings about fluctuation in CGM strengthen the indication of glycemic variability as a predictor of achievement of glycemic target.

5. Conclusion

Both age, smoking status, HbA_{1c} , 1,5-AG and CGM fluctuation are at baseline for people with type 1 diabetes who succeed or fail to achieve glycemic target after 16 weeks of treatment. These are valuable findings prior to development of an algorithm to predict people who do not achieve glycemic target from intensive insulin treatment where alternative treatment options should thus be considered.

Translating openEHR Models to FHIR

Georg FETTE^a, Max ERTL^a, Stefan STÖRK^a

^a*Comprehensive Heart Failure Center, University Hospital of Würzburg, Germany*

Abstract. openEHR and FHIR are two competing clinical data modeling and data exchange standards, that are commonly seen as mostly incompatible. However, the two have quite much in common and bridging approaches between the two worlds can serve the benefit of both communities. In the presented work, the data models of openEHR are translated into FHIR data models.

1. Introduction

FHIR and openEHR are two data model standards, which both have in common to use two-layer-modelling [1], i.e. they specify a meta-model, which is used to specify the domain model. If it were possible to translate openEHR models to FHIR models, many software components from the FHIR domain could be used to process openEHR data. Bosca [2] already described the possibility of using FHIR profiles as a reference model for openEHR and translating openEHR models to StructureDefinitions. The presented work analyzes to what extent an openEHR model can be generically and preferably without loss of information transformed into a FHIR model.

2. Methods

For the translation of an openEHR model all model parts of a given openEHR system (RM, archetypes, templates) are translated to StructureDefinitions. The set of StructureDefinitions representing the RM was created by hand. The ADL files of archetypes were parsed and all types inside fields were translated to individual elements of the translated StructureDefinition. The object-composition paradigm was realized by using BackboneElements. All elements of the anonymous class that represents a constrained archetypes element (as well as elements inherited from the RM type) were explicitly added to the BackboneElement. The identification of identifiable openEHR list elements was realized by incorporating the identifier into the path of the FHIR element. The cardinalities of elements were ignored and only the occurrences of the contained types were translated to FHIR. The translation of openEHR templates was realized by using the template format OET as translation source. The template files were parsed and for each contained archetype a FHIRPath constraint was added that required the existence of the element. All further constraints on the contained archetypes were also realized via FHIRPath constraints and added to the template model's root element. The described translation methodology was implemented and applied on the models on the international CKM.

3. Result

The translated archetypes and templates were successfully translated to StructureDefinitions and were validated without errors. By realizing the sub elements of archetypes as BackboneElements, the RM type of these elements was lost.

4. Discussion

The archetype translation was modeled using BackboneElements and by explicitly expanding the anonymous classes representing the archetype elements. The necessity to expand the anonymous classes make the logical models look quite bloated and complex when the used RM types themselves contain many elements (e.g. most RM types used in archetypes derive from LOCATABLE, which already adds 6 elements).

The template translation was modeled alternatively using FHIRPath constraints to realize object-composition. This solution has the drawback that type checking could become complicated, because the actual elements are not explicitly defined. Although FHIR validators are capable of checking these constraints, this option moves the workload of conformance checking to the FHIRPath part of the validator, which could probably reduce performance.

The OET format is commonly only used during template design time. It was developed for the Ocean Template Designer and is no official openEHR format. However, it has the advantage that all object-compositions and constraints on elements are still explicitly listed so they can be directly translated to FHIRPath constraints.

When using FHIR it is forbidden to create a new set of custom profiles. It creates systems that are semantically incompatible with other FHIR systems not using those models. The presented work aims purely on the one-to-one model translations and semantic mappings are not its scope.

5. Conclusion

An approach was presented to translate openEHR archetypes and templates to FHIR logical models. The approach was tested on the models contained in the international openEHR model repository CKM. The authors consider the translation of openEHR models to FHIR models a difficult issue, because the two standards use different object-composition, derivation and constraining paradigms. Either the resulting models contain a very large number of elements or the number of resulting models becomes very large.

Uncovering Care Barriers Experienced by Patients and Loved Ones in the Emergency Department: Can a Health App Help?

Azzra MANGALJI^{a,1}, Kendall HO^{a,b,c}, Wayne CHOI^{a,b}, Chad KIM SING^{a,b}, Heather LINDSAY^{a,b}, Christopher Wai-Chung LEE^{a,b}, Kent LOFTSGARD^d, Michael LIM^c, and Nooshin JAFARI^c

^d British Columbia Support Unit, Vancouver BC, Canada

Keywords. emergency department, care barriers, health technology, health app, patient satisfaction

1. Introduction

There are approximately 13.9 million ED visits in Canada each year. These visits can be overwhelming for patients and their loved ones. This study aimed to identify factors that diminish the ED experience for patients, guiding us to identify care barriers and informing us how to design and implement a person-centred app for patients visiting ED.

2. Methods

This mixed-methods study involved an online survey (n=125), focus groups (n=16) and individual interviews (n=14). Participants were patients and accompanying family or friends over 19 years who had visited any ED in BC in the past five years (June 2014 – June 2018). The survey, representing 169 visits to the ED, contained questions based on common care barriers identified in our pilot study[1] and past literature.

3. Results

Overall, 67.4% of interview patients were satisfied with the quality of care. However, we identified 5 ED care barrier themes presented below in order of prevalence of comments: **Overall Experience (34.1%)**: 44.3% felt communication challenges with ED staff, and 35.1% felt their care was unsatisfactory at one or more points during their visit.

Wait times (25.7%): Most (35.8%) spent 1-3 hours waiting to see a doctor, and 18.2% spent more than 10 hours total in the ED.

Discharge process (15.7%): 63.9% of the participants felt they were mentally and physically ready to manage their condition at home, whereas 36.1% were not.

¹ Corresponding author E mail: azzra.mangalji@alumni.ubc.ca.

Information Exchange (14.5%): Participants felt they did not receive enough information about amenities (74.6%), wait time (71.5%), wait reason (58.5%), who was going to be seeing them (56.6%), and aftercare instructions (52.4%).

Process Flow (10.0%): 64.7% of these participants were unclear as to next steps as they progressed through the ED, and 35.3% desired improvement in efficiency.

Use of Technology: When asked whether they felt an app would be helpful in their ED journeys, 47.5% of survey participants were sure they would use it, and 38.3% would decide depending on the functionality. Overall, 86.7% of interview participants wanted to use such an app if it existed, and those who were reluctant reported reasons such as security concerns and it being overwhelming to be a patient and expected to be on their phone.

4. Discussion

The care barriers identified were about timely communication, but were unrelated to the satisfactory quality of care experienced by the majority of patients. Suggested improvements that emerged were related to adjusting communication and administrative efforts, as follows:

Improving physician-patient communication: Interpersonal skills during communication ensures patients feel being the focus of care, aided with practical solutions such as physician name tags and context-appropriate touch

Improving patient experience of waiting: Electronic notifications to patients for their turn to see a physician untethers them from the waiting room. Furthermore, periodic checking to update patients of wait times or, “ED rounding,” can improve satisfaction, reduce frustrations, and decrease patients leaving prematurely.

Improving patient anticipation of ED journey: Providing a general road map to prepare patients for their journeys through the ED and updating them on what they are waiting for can help decrease logistical confusion and ease unrest.

Improving patient preparedness to manage their health post-discharge: Providing documentation of discharge summaries and home management information for patients to review at home can reduce anxiety, improve adherence to therapies and follow-up, and reduce unnecessary ED revisits.

It is important to note that ED overcrowding, experienced by most EDs, can compromise communication over delivery of quality care as health professionals have finite time. Therefore, solutions that support better communication and improve ED flow would be ideal.

5. Conclusion

We are now developing an ED app based on the priority care barriers identified, which are likely similar in other EDs. We aspire to have this app to be useful and scalable to other locations to optimize person-centred care.

Usability Issues with Mechanical Ventilation Devices

Beatrice COLDEWEY^a, Annette DIRUF^b, Rainer RÖHRIG^a
and Myriam LIPPRANDT^{a,1}

^a*Institute of Medical Informatics, Medical Faculty, RWTH Aachen University, Germany*

^b*Division for Medical Informatics, Carl von Ossietzky University of Oldenburg, Germany*

Abstract. The user interface of a mechanical ventilator is safety critical, as use errors can lead to patient harm. A systematic review was conducted to identify published usability issues and contributing factors that can lead to use errors. The findings were grouped in an Ishikawa diagram. Many of the problems mentioned based on inconsistent labeling and manufacturer-specific naming of ventilation modes. In the studies, usability was often measured quantitatively and did not allow any conclusions to be drawn about concrete problems.

Keywords. Ventilators, mechanical; usability problems; patient safety

1. Introduction

Due to technological progress in the medical field, more and more functionalities of mechanical ventilators lead to an increase in complexity, which is reflected in the user interface. To reduce use-associated risks, the application of usability engineering to medical devices is subject to legal regulations [1]. Despite use of approved equipment, use errors caused by perception, cognition or action error can cause adverse events with potential patient harm. The aim of this work is the systematic analysis of published usability issues and contributing factors that can lead to use errors described in literature.

2. Methods

A systematic review according to the PRISMA reporting standard was carried out. In PubMed a search string consisting of a combination and synonyms of the terms "mechanical ventilation", "usability" and "risk" was used to find eligible publications. Articles were included if detailed information on usability issues and contributing factors as cause for reported incidents or possible use errors with mechanical ventilation devices was given. The selected articles were qualitatively analysed by two independent researcher. The findings were systematically listed in an Ishikawa diagram by the occurring main categories.

¹ Corresponding Author.; mlipprandt@ukaachen.de

3. Results

3.1. Study Selection

The search strategy returned 379 articles. The titles and abstracts were assessed based on the inclusion and exclusion criteria leaving 31 studies for the full text screening. Two papers could not be obtained as full text. After reading the remaining articles, 19 papers were omitted due to exclusion criteria. There are 10 articles left after this procedure.

3.2. Use Error Analysis

The 10 articles eligible for inclusion deal with the usability evaluation of ventilators and approaches for alternative forms of presentation as well as the analysis of critical events. The main causes for use errors were inconsistent labelling of the ventilation settings and parameters across different devices (e.g. manufacturer / language specific terminology), aspects of the design (e.g. the position of the power switch, the design of interaction elements like buttons or the complexity of and divergent interaction models cross different devices) and the absence of experience and training according to manufacturer specification with the ventilators [2–5].

4. Discussion und Conclusion

This review showed that there are several usability issues related to mechanical ventilation systems described and discussed in the current literature. The terms usability and user error were not used uniformly. Most of the articles have dealt with the usage of the devices, but not with the causes of the use errors. Many of the found usability problems were caused by inconsistent labelling across the devices and different manufacturers [2–4]. Therefore, the implementation of an internationally standardized nomenclature for ventilation modes and parameters is recommended [2–4]. Most of the studies focused on quantitative methods and statistical evaluations. Potential causes were given only as examples as explanation for the quantitative results in the discussion. For the analysis of use errors new testing methods and a systematic causal analysis should be performed. Further investigation on usability problems of mechanical ventilators and contributing factors is recommended.

User Satisfaction with a Speech-Enabled Translator in Emergency Settings

Antony Akash JANAKIRAM^a, Johanna GERLACH^b, Alyssa VUADENS-LEHMANN^a, Pierrette BOUILLON^b and Hervé SPECHBACH^a

^a Geneva University Hospitals, Department of Community Medicine, Geneva, Switzerland

^b Faculty of translation and interpreting (FTI), University of Geneva, Geneva, Switzerland

Abstract. In medical emergency situations, the language barrier is often a problem for healthcare quality. To face this situation, we developed BabelDr, an innovative and reliable fixed phrase speech-enabled translator specialised for medical language. Majority of participants (>85%) showed a positive satisfaction level using BabelDr.

Keywords. Fixed phrase speech-enabled translator, web application, user satisfaction, emergency settings

1. Introduction

Following the refugee crisis, European hospitals are increasingly confronted with patients who have no language in common with the medical staff. At the Geneva University Hospitals (HUG), 52% of the patients are foreigners and 8% speak no French at all. Miscommunication is a known threat to quality, security and equitability of medical care [1, 5]. Professional interpreters are not always available in emergency settings and considered to be expensive [2]. Generic technologies such as Google Translate (GT) are not reliable enough [3]. Medical fixed phrase translator lack of usability. In this context, the HUG in collaboration with the FTI, supported by the Private foundation of HUG, developed BabelDr, a speech-enabled fixed-phrase translator. Like other systems, it relies on pre-translated sentences, but includes speech recognition, allowing doctors to freely ask questions instead of searching for them in a list. Pretest showed that BabelDr is significantly more precise than GT and presents higher usability than MediBabble [4]. The aim of the present study is to evaluate BabelDr in real emergency settings. We focus on two aspects: global user satisfaction and the perceived quality of patient-doctor communication through the system, from the patient's and doctor's point of view.

2. Method

Patients were recruited between January and August 2019 in the outpatient emergency unit of the HUG. Inclusion criteria are: patients must speak a language available on BabelDr and must not have a French level sufficient for a standard diagnostic interview.

Patients are recruited in the outpatient emergency unit of the HUG. Exclusion criteria are patients who aren't able to read in their language. Each doctor followed a short training before using BabelDr. Participants are enrolled during daytime, fill a consent form and receive instructions on how to interact with the tool. During the consultation, the use of the tool can be interrupted by the doctor or the patient. Doctors can use the speech recognition system or directly select sentences in a list to ask their questions and the patients are required to answer non-verbally. After the consultation, all participants (doctors and patients) fill in a satisfaction survey paragraph.

3. Results

In total, 22 patients (age: $M=41.18$, $SD=17.44$) are eligible for this study and speak: Spanish (9), Arabic (4), Farsi (6), Tigrinya (2) and Albanian (1). Results on the satisfaction level show predominantly a positive feedback from both patients and doctors (>85%). Regarding patient-doctor communication, 68.2% of patients think the system allows them to completely explain the reason for consulting and 90.1% of doctors think BabelDr allows them to understand the patient's problem.

4. Discussion

We observe that most patients are able to communicate their reason to visit and doctors mostly understand the problem, suggesting that BabelDr is suitable for communication in emergency settings. User satisfaction is higher for patients than doctors, who can feel constrained by the available questions. Patients' dissatisfaction is related to misunderstood translations (due to level of literacy, text-to-speech quality and dialects).

5. Conclusion

Based on the remarks of patients and doctors, we continue to develop the tool by expanding coverage and adding more languages. A bidirectional system, allowing patients to answer by selecting pictograms, is also in development.

Abstract. Multimorbidity increases care needs among people with chronic diseases. In order to support communication between patients, their informal caregivers and their healthcare teams, we developed CONCERTO+, a patient portal for chronic disease management in primary care. A user-centered design comprising 3 iterations with patients and informal caregivers was performed. Clinicians were also invited to provide feedback on the feasibility of the solution. Several improvements were brought to CONCERTO+, and it is now ready to be implemented in real-life setting.

Keywords. Patient portal, Chronic disease management, User-centered design

1. Introduction

Chronic diseases are the leading cause of mortality in the world, and account for nearly 70% of deaths [1]. Interventions increasing patient involvement in their own care are associated with better health outcomes [2]. eHealth technologies have the potential to support chronic disease management by considering end-users' needs, preferences, and capabilities. CONCERTO+ is an innovative solution to improve patient experience and includes personalized follow-up, health education, appointment management, and communication between patients, informal caregivers and primary healthcare teams.

2. Methods

The development of CONCERTO+ was done through a collaborative approach between patients, caregivers, researchers, clinicians, designers, and IT developers who identified the functionalities to include. The solution was developed through 3 phases, based on user-centered design methods [3], and usability was assessed with patients.

3. Results

- Phase 1: Development of the 1st prototype by a design team based on a review of available solutions. Usability test performed with 10 patients and informal caregivers using think-aloud and eye-tracking methods.
- Phase 2: Design of the 2nd prototype, addition of graphics and more functions. Usability tested with 9 people with a lower education level. Generally positive comments on CONCERTO+, and some improvements suggested.
- Phase 3: 3rd prototype designed in response to the results of the 2nd usability test. A 3rd usability test will be done to make the final adjustments to the solution.

4. Discussion

Users generally found CONCERTO+ intuitive and easy to navigate. After 2 iterations, only minor changes were brought to the design, although improvements are still possible in the final version. Chronic patients and their informal caregivers are willing to use CONCERTO+ to communicate with their primary healthcare team.

5. Conclusion

The final prototype will be translated into a fully interactive application with the support of our IT partners. A pilot trial will assess the feasibility of a large-scale study.

Using Long Short-Term Memory (LSTM) Neural Networks to Predict Emergency Department Wait Time

Nok CHENG^{a,1} and Alex KUO^a

^a School of Health Information Science, University of Victoria, Canada

Abstract. Emergency Department (ED) overcrowding is a major global healthcare issue. In this paper, we used Long Short-Term Memory (LSTM) recurrent neural networks to build a model to predict ED wait time in the next 2 hours using a randomly generated patient timestamp dataset of a typical patient hospital journey. Compared with Linear Regression model, the average mean absolute error for the LSTM model is decreased by 15% (3 minutes) ($p < 0.001$). The LSTM model statistically outperforms the LR model, however, both models could be practically useful in ED wait time prediction.

Keywords. ED Overcrowding, ED Wait Time Prediction, Machine Learning, Linear Regression, Recurrent Neural Network, Long Short-Term Memory

1. Introduction

Emergency Department (ED) overcrowding is a complex, systemic and global healthcare issue resulting in decreased care efficiency and worsening patient outcomes [1]. ED wait time, defined as the time to physician initial assessment, can support decision making to enhance patient experience and improve hospital resource allocation [1]. Very limited research studies explore the use of *Long Short-Term Memory (LSTM) Recurrent Neural Networks* [2] in Emergency Medicine research, while LSTM has been commonly used in fields such as Business consistently providing more accurate sequence predictions [3]. Comparatively, *Linear Regression* (LR) is a popular and simple prediction method, but such a method may not be accurate in the complex ED overcrowding problem. The aim of this paper is to preliminarily investigate the application of the LSTM method in ED overcrowding analysis by comparing the prediction accuracy of ED wait time in the next 2 hours of an LSTM model and that of an LR model.

2. Methods

A dataset was created to represent 50,000 patient instances of timestamp differences randomly generated over a pre-defined range uniformly. A sequence of five (5) timestamp differences were used to illustrate the six (6) timestamps in a patient journey,

¹ Corresponding Author, Nok Cheng, School of Health Information Science, University of Victoria, HSD Building, A202, Victoria, B.C., Canada; E-mail: nokcheng@uvic.ca.

including: patient arrival time, triage time, registered time, physician initial assessment time, ED exit time, and inpatient unit discharge time. The average ED wait time for the next 2 hours was calculated in minutes. Two models were built: 1) a single-layered LR model with an input array of 1×5 for the 5 timestamp differences; and 2) a single-layered LSTM model consisting of 5 input units corresponding to the 5 timestamp differences in the sequence with the final unit outputting to a linear regression layer. Both models were trained and validated with 80% of the data using 100-Fold Cross Validation and tested with the remaining 20% of the data. Both models include an early stopping to prevent overtraining and use mean absolute error (MAE) as loss function. A two-sample t-test was performed on the MAE values from the testing phase with a significant difference of $p < 0.001$ and 99% confidence level.

3. Results

The LSTM model achieved a 15% (3 minutes) lower average MAE ($p < 0.001$), 7.49×10^{-2} (99% CI $5.57 \times 10^{-2} - 9.40 \times 10^{-2}$) (17 minutes) compared to 8.84×10^{-2} (99% CI $7.27 \times 10^{-2} - 10.41 \times 10^{-2}$) (20 minutes) in the LR model.

4. Discussion

Supported by Tax et al. 2017 [13], the LSTM outperforms the LR due to its ability to learn the relationships between each consecutive time-step. The 3-minute prediction difference between the 2 models suggests that either of the 2 models could be practically useful in wait time prediction. An ED wait time prediction model is a beneficial clinical decision support tool to provide patients control in their decision making of ED care [4], and improves care efficiency with proactive allocation of resources such as increasing workload nurses and overflow units [1]. A major limitation of the study is the use of randomly generated dataset without real patient flow and data quality representation.

5. Conclusion

Though the LSTM model statistically outperforms the LR model, both models could be practically useful in wait time prediction. Next steps include using broader patient data variables from a level 1 trauma hospital to explore different LSTM and/or deep neural network architectures and compare with various accuracy evaluations.
